Lung cancer is a rare disease in Iceland, being less in frequency among carcinomas of various organs according to an analysis of necropsy findings.

The increased frequency of lung carcinoma in civilised countries is thought to be connected with

ase in the consumption of cigarettes which has taken , particularly in Great Britain and the USA g this century

Iceland cigarette smoking, though practised since beginning of this century, has increased at a much er rate than in other countries, and the annual umption did not reach 1 lb per head until 1945, eas in Great Britain and Finland it passed that unt before 1920

it takes twenty twenty five years to develop lung er from smoking cigarettes these differences in con ption will explain why lung cancer is still rare in and.

the last few years the annual consumption of rettes in Iceland has reached 1.5 lb per head, and if above assumption is correct a considerable rise in the dence of lung carcinoma may be expected in 1960-65

PROTECTION OF THE SKIN FROM SUNBURN

COMPARISON OF THE ABSORPTION SPECTRA OF SCREENING AGENTS AND THEIR EFFICACY IN ECZEMA SOLARE

BRIAN RUSSELL

M.D. Lond., M.R.C.P., D.P.H.

ASSISTANT PHYSICIAN TO THE SKIN DEPARTMENT,

INITIAL ASSISTANT IN SKIN DEPARTMENTS, ROYAL FREE AND
 ST JOHN'S HOSPITALS

In the prevention of skin disorders caused by sunlight and the relief of those aggravated by light it is useful to know what spectral range of light must be excluded. Most of these disorders the wave lengths concerned are shorter than 3300 Å but longer than 2900 Å which is about the short wave length limit of the summer sun temperate zones. In this category fall acute and chronic solar dermatitis, light sensitisation by sulphonamides and some other substances, xeroderma pigmentosum, and the initiation or aggravation of lupus erythematosus, herpes simplex recurrens, keratoses, and in cancer. Most cases of eczema solare of Willan and summer prurigo of Hutchinson, which are now often lumped together as the "polymorphic light eruption" (Harthausen, are also caused by this "sunburn spectrum" (fig 1), though in others violet and blue rays may play a part.

Urticaria solare is usually due to sensitivity to the violet (3000-5200 Å), but cases have been reported in wave lengths shorter than 3700 Å. Window-glasses allow all rays of wave length shorter than 3130 Å, so gives complete protection against most of the first group of disorders, but none against urticaria solare, except the rare form in which the skin is sensitive to wave lengths under 3700 Å (Beal 1948) and which may be partially relieved.

A patient with eczema solare, apparently due to the spectrum within the sunburn spectrum range, has been

Fig. 1—Action spectra of some solar dermatoses (adapted from Glasser 1944 and other sources). Ordinate units have been chosen to bring all maxima to same level. SS and WS = distribution of sunlight at noon in midsummer and midwinter.

B & P = sunburn and pigmentation

PP = darkening of preformed pigmentation.

U₁ and U₂ = urticaria solare blue-violet type and <3700 Å type (Beal)

GT = lower limit of transmission by window glass.

tested with several screening agents incorporated in different bases, and the absorption spectra of various combinations of bases and chemical screens have also been determined for comparison with the clinical findings.

CASE REPORT

A male civil servant, aged 58 had for 15 years suffered at intervals from intense itching of the forehead, cheeks, chin, and backs of the hands, followed by erythema and a papulo-vesicular eruption. The condition always began in May or June and cleared in September and the itching and eczematous reaction started 6-8 hours after exposure to sunlight. For 2 years the trouble had been more widespread, affecting the back of his neck and his forearms if they were uncovered.

There was no history of the application or ingestion of sulphonamides or of the application of tar or acriflavine, but in 1929 he was treated for sores in the nostrils with soap and an ointment, both of which contained mercury, and after their use a rash appeared on his face. In July, 1935, he had a carbuncle which was treated with mercurial tablets by mouth. This treatment was followed by swelling of his face and a rash on his face and hands which immediately preceded the onset of his recurrent summer eruption.

The patient's mother, a daughter of one of his sisters, and his niece's daughter all suffered from light sensitivity, the ages of onset being 50 years, 29 years and 1 year.

Condition on Examination (Sept. 22, 1949).—A healthy-looking grey haired man with a patchy squamous erythema involving his forehead, the backs of his hands, and to a lesser degree his nose and cheeks. A diagnosis of eczema solare was made with a presumed genetic basis precipitated by sensitisation to mercury, and possibly associated with some disturbance of liver function.

Laboratory Findings.—Blood Wassermann and Kahn reactions negative. Mantoux reaction (1 in 10 000) positive.

Total serum proteins 6.59 g per 100 ml., serum-albumin 4.39 g and serum globulin 2.2 g per 100 ml., albumin globulin ratio 2:1.02.

Alkaline phosphatase 4.5 King Armstrong units. Thymol turbidity test, normal (less than 1 unit). Blood urea 45 mg per 100 ml.

Urine acid ether U.V.R. test, negative.

Faeces: no porphyrins detected spectroscopically by Snapper's test.

Light Sensitivity.—Exposure of the patient's forearm to a mercury vapour lamp for 1 min. at 28 inches (first-degree exposure) produced a fourth-degree erythematobullous reaction equivalent to that produced in the average subject by a similar exposure for 4 min. or more. The eczematous reaction, which was followed by peeling and well marked pigmentation indicated fourfold to sixfold enhancement of sensitivity to the spectrum from a mercury vapour lamp which is strong in sunburn wave lengths but weak in the longer wave lengths of sunlight. It is hoped shortly, by exposing the patient's arm to light which has passed through a spectrograph to define the region of the spectrum to which his skin is susceptible. The evidence so far gathered suggests that the sensitivity is to the sunburn range.

Test for Passive Transfer of Sensitivity.—As was expected, the Fraumitz-Kuestner reaction was negative (a) with blood

serum and (b) with blister fluid. The tests were carried out as follows

(a) Blood was taken from the patient, separated, and the serum pipetted off. Part of this serum was inactivated by heating for an hour at 60°C. A control subject was given intradermal injections of (i) 0.2 ml of the unheated serum and (ii) 0.2 ml of inactivated serum into two areas on the flexor surface of the forearm. These two areas and a third area of normal skin were then irradiated with a first-degree erythema dose of ultraviolet light. Into a fourth area on the forearm 0.2 ml of unheated serum was injected as before but the area was irradiated (first-degree erythema) after an interval of four days. A first degree erythema developed in all four areas.

(b) Blister fluid was obtained from a bulla produced on the patient by irradiation with the Kromayer lamp. The procedure was then the same as with the serum. The area injected with active blister fluid became irritating after six hours and the irritation persisted for twenty-four hours. A first-degree erythema was produced in all the areas.

TESTS WITH SCREENING AGENTS

It was found that an area of skin could be completely protected against an exposure to a mercury vapour lamp sufficient to cause an erythematovesicular reaction on unprotected skin by covering it with a film about 0.1 mm thick of the following anhydrous emulsifying base "A," as used at St John's Hospital for Diseases of the Skin.

Lanette wax (sx)	6.25
Liquid paraffin	6.25
Yellow soft paraffin	87.5

The screening effect of this base is probably due to the high percentage of yellow soft paraffin.

Four different substances—(a) tannic acid 5%, (b) quinine hydrochloride 5%, (c) sodium *p* aminobenzoate 10%, and (d) salol 10%—were incorporated in the following five different bases:

- Ointment of wool alcohols
- Water
- Yellow soft paraffin.
- Hydrous base "C," containing lanette wax (sx) 3, liquid paraffin 6, water 91
- Anhydrous base "A" (as above)

These were applied to areas of skin in a film about 0.1 mm thick, except the watery solutions and suspensions which were painted on. The areas were then exposed for 1 minute to the mercury-vapour lamp at 28 inches, an exposure previously noted to produce an erythematovesicular reaction on uncovered areas.

The results can be tabulated as follows, where 0 = no reaction, 1 = slight erythema, 2 = moderate erythema with some swelling, and 3 = marked erythema with vesiculation.

Substances		Bases				
		i	ii	iii	iv	v
(a)	(a)	1	3	1	1	0
	(b)	1	3	1	1	0
	(c)	2	3	0	0	0
	(d)	1	3	0	1	0
Base alone		3	3	0	2	0

Conclusions—Yellow soft paraffin and an anhydrous emulsifying base containing 87.5% of yellow soft paraffin are effective screens against sunburn. A hydrous emulsifying base is slightly effective and its effects are enhanced by the addition of screening substances. Ointment of wool alcohols is ineffective alone but almost as effective as the hydrous base when screening agents are added. Watery solutions and suspensions of screening substances are all ineffective. This is not always due to their insolubility in water because tannic acid and sodium *p* aminobenzoate are very soluble. Salol, on the other hand, is almost insoluble, while quinine hydro

chloride is only soluble 1 part in 32 of water. acid 5% and quinine 5% seemed to lessen screening properties of the yellow soft and sodium *p* aminobenzoate did not influence

ABSORPTION SPECTRA

The absorption spectra of various creams with a Hilger quartz spectrograph, the light a high voltage spark from metal electrodes exposure time 30 seconds. The light was each cream in a film spread as uniformly 0.15 mm thick between two thin layers of unevenness of some bands is due to the getting an extremely thin layer free from local

Bases Alone and with Sodium *p* Aminobenzoate
Sodium *p* aminobenzoate was incorporated in bases because in recent years *p* aminobenzoic acid and its esters have been widely used as sun screening agents. Just as in the clinical tests, this substance was found to improve the screening properties of four out of

Fig 2—Absorption spectra of five different emulsifying bases alone and with 15% sodium *p* aminobenzoate (Na P.A.B.)
I and II: base "C" alone and with Na P.A.B.
III and IV: ointment of wool alcohols alone and with Na P.A.B.
V and VI: base "B" alone and with Na P.A.B.
VII and VIII: witch hazel cream alone and with Na P.A.B.
IX and X: base "A" alone and with Na P.A.B.

five bases, the exception being the anhydrous emulsifying base "A" which was fully effective by itself in the 2900–3300 Å range.

The bases were effective in the following order:

The bases were effective in the following		
Anhydrous base "A"	Completely effective	
Ointment of wool alcohols	} Relatively ineffective	
Witch hazel cream (B.P.C.)		
Anhydrous base "B," containing	} Ineffective	
lanette wax (sx)		30
liquid paraffin		40
white soft paraffin		30
Hydrous base "C"		
and with sodium <i>p</i> aminobenzoate incorporated		
Anhydrous base "A"	} Completely effective	
Witch hazel cream (B.P.C.)		
Ointment of wool alcohols	} Relatively effective	
Anhydrous base "B"		
Hydrous base "C"		

It is clear that in a light screening cream the role plays a part as important as any screening agent that may be incorporated. Apart from the anhydrous base "A," which was completely effective in itself, the most successful base in conjunction with sodium *p* aminobenzoate was pasta hamamelidis (witch hazel cream B.P.C.), a "vanishing" cream consisting of 50% solution of witch hazel in pasta acid stearici, a non greasy stearate cream. This base has the added virtue of cosmetic quality, and it is non staining, non irritant, free from rancidity, sufficiently adhesive but can easily be washed off if desired, and does not interfere with heat. Unfortunately pasta hamamelidis may be "cracked" by some screening agents—for example, tannic acid.

3—Absorption spectra of vanishing-cream base alone and with 5% of six different screening agents: I. base D alone, II. with quinine hydrochloride, III. with tannic acid, IV. with Na P.A.B., V. with yellow soft paraffin, VI. with pyribenzamine, VII. with salol

following vanishing-cream base "D" is of equally good cosmetic quality but more stable, and makes an excellent fine emulsion

Stearin	25
Triethanolamine	1
Glycerin	10
Oil of theobroma	1
Cetyl alcohol	0.5
Distilled water	62.5

(To be dispensed in an airtight container)

Vanishing-cream Base "D" Alone and with Six Screening Agents (fig 3)

When six screening agents were added to base "D" at a concentration of 5% and the order of effectiveness found to be

base "D" with tannic acid	Effective
" " quinine hydrochloride	
" " pyribenzamine	
" " sodium <i>p</i> -aminobenzoate	Relatively effective
" " salol	
" " base alone	Ineffective
" " with yellow soft paraffin	Aggravating

The slight leakage with sodium *p* aminobenzoate was probably due to faulty spread, since it only occurred in half or less of the band and in subsequent absorption spectra the cream was found to be fully effective when contained 5, 10, or 15% of sodium *p* aminobenzoate or 2.5, 5, or 10% of tannic acid, but not completely effective with 12.5% of tannic acid. The aggravating effect produced by the incorporation of yellow soft paraffin, which was intense with 5%, was noted in a lesser degree with 12.5 and 25% of paraffin, but with 50% this cream had a screening effect as complete as that of emulsifying base "A" (containing 87.5% yellow soft paraffin) or of pure yellow soft paraffin. It is important to bear in mind this potentially aggravating action that may result from the incorporation of 25% or less of yellow soft paraffin in emulsifying bases.

Conclusion and Clinical Confirmation—The incorporation of tannic acid, quinine, pyribenzamine, or sodium aminobenzoate in vanishing cream base "D" makes an effective non greasy preparation. Salol was found to be slightly less effective in a strength of 5%, but Luckiesh et al. (1940) found perfect absorption in the 2967–3022 Å range with 10% of this substance.

The patient was next irradiated with suberythematous erythema 1, 2, and 3 exposures from a mercury vapour lamp after areas of skin had been covered with a layer 0.1 mm thick of one of two creams containing 5% of tannic acid and 5% of sodium *p* aminobenzoate respectively in the vanishing cream base "D". For each cream there were four areas, 5 cm square, and 1 ml of cream was spread over the whole area of 100 sq cm. Figure 4 shows that both creams gave complete protection at all exposures. The erythematovesicular reaction at

the border of the protected areas was much greater with the longer exposures.

DISCUSSION

The prevention of sunburn in normal people from over exposure to sunlight is a simpler matter than the protection of a light sensitised person, because in the former we are dealing with healthy skin whereas in the latter the skin is already affected in some way. The sufferer from eczema solare, lupus erythematosus, herpes simplex recurrens, or hydroa is often less tolerant than the normal person to the local application of chemicals as well as to sunlight. This possibility must be borne in mind when prescribing for lesions already present which have resulted from moderate sun exposure. The patient should be warned that it is impossible to forecast whether a preparation will or will not be tolerated, so that trial and error methods have to be adopted. The history may indicate the advisability of using one substance rather than another, and the simpler the formula the less is the chance of producing sensitisation reactions and, if they do occur, the easier it is to determine the sensitising agent.

Yellow soft paraffin is an effective screening agent by itself, but it is cosmetically impracticable and its immiscibility with water makes it occlusive and liable to impair sweat evaporation. On the other hand, emulsifying bases containing 50% of yellow soft paraffin are also effective and are cosmetically more practicable, though still rather greasy. Eczematous reactions may occasionally arise from lanette wax used as an emulsifying agent.

Rothman (1942) reported that *p* aminobenzoic acid and its esters were as effective as tannic acid and more

Fig 4—Patch test with ultraviolet light. Above patient's back after exposure. Below key: Areas E3 were exposed for 3 min 45 sec; E2 for 1 min 52 sec; E1 for 45 sec; and SE for 30 sec.

stable, besides being non staining, odourless, colourless, easily miscible, and non irritating. Nevertheless, Baer and Meltzer (1948) have reported sensitisation to monoglyceryl *p* aminobenzoate in a patient who had previously developed eczematous sensitivity to benzocaine and sulphonamides. Subsequent patch tests revealed hyper sensitivity to unsubstituted *p* aminobenzoic acid, aniline, paraphenylenediamine, procaine, sulphaguanidine, and a number of other related compounds. If, as they suggest, this was cross sensitisation to chemically related compounds, it means that *p* aminobenzoic acid or its esters should not be used for the treatment of light sensitisation states which may possibly have been caused by sulphonamides or related substances.

Pyribenzamine has also been reported to cause a severe eczematous reaction when applied in a strength of 2% (Strauss 1948). Sulzberger et al (1948) reported two cases of eczematous reaction among 90 patients for whom this substance was prescribed. Baer et al (1948) think that its use is indicated only in selected cases where its combined antipruritic and light filtering action is especially necessary. Quinine occasionally produces sensitisation reactions of such severity that its use is hazardous except under strict supervision.

Benzyl, menthyl, and sodium salicylate have their advantages, and phenyl salicylate (salol) has been described by Luckkosh et al (1946) as non irritating and non toxic, and giving perfect absorption in a 10% preparation. However, salol in tooth powders has been reported to cause eczema of the lips (Sollmann 1948). It is gradually decomposed by alkalis into phenol and salicylic acid, but the liberation of phenol on the skin from contact with alkalis, though a possible cause of eczema, seems an unlikely occurrence. Tannic acid 2.5-5% is usually well tolerated and is sometimes used in the treatment of eczema. Phenazone is said to be effective (Quiroga et al 1948) but has sensitising potentialities.

The vehicle in which the screening agent is to be incorporated must be chosen with care, not only for its emulsifying qualities, on which the effective presentation of the screening substance depends, but also as regards possibly sensitising constituents. Thus cream "D," though an excellent emulsion and more stable than pasta reidi stearici or pasta hamamelidis, may occasionally not be tolerated because of its triethanolamine content.

Creams are the best vehicles, cosmetically, but Luckkosh and colleagues (1946) point out that in some circumstances they are too easily washed off the skin, which thus loses its protection. Any base containing water may break down at freezing temperatures and so be useless in cold climates. Alcoholic solutions have been recommended, and Shaw (1946) found the application of a 5-10% solution of *p* aminobenzoic acid in 70% alcohol highly effective in protecting people with lupus erythematosus. Tannic acid and quinine both dissolve well in alcohol, and salol will make a 6.6% alcoholic solution. Pillsbury et al (1946) recommend the following with the warning that it will stain white clothing.

Tannic acid	12 g or ml
Phenyl salicylate	8
Glycerin	8
Alcohol (70%)	to 40

In addition to these chemical parasols, some relief may be obtained from physical screens in the form of calamine, zinc oxide, bismuth subcarbonate, titanium dioxide, ichthammol, or insoluble pigments in face powders and grease paints. All these preparations are cosmetically less desirable because more obvious to the observer than chemical screens in vanishing cream bases. Nevertheless, they offer the best protection against solar urticaria because the chemical screens are ineffective

against the longer visible wave lengths usually r for this rare condition. These two formulae are used.

(1) Calamine (B.P.)	15 g or ml
Zinc oxide	5
Bentonite *	2
Glycerin	5
Distilled water	to 100
(2) Titanium dioxide	15 g or ml
Bentonite	10
Glycerin	5
Distilled water	to 100

* Bentonite is a colloidal clay with emulsifying properties.

The addition of anti histamine drugs to light screening creams is not only ineffective but undesirable, with the exception of pyribenzamine which is useful because of its powers of absorption of the sunburn spectrum and not from its anti histamine action. There is no evidence that anti histamine drugs given by mouth will prevent sunburn or relieve eczema solare. Rubin et al (1947) however, reported relief of urticaria solare from administration of pyribenzamine by mouth.

SUMMARY

Protection against the sunburn spectrum is provided by a vanishing cream type base containing tannic acid 5%, quinine hydrochloride 5%, pyribenzamine 5%, sodium *p* aminobenzoate 10%, salol 10%, or yellow soft paraffin 50%. Any one of these creams may be used to prevent sunburn, but tannic acid is the first choice.

When these substances are used in the treatment of eczema solare and other light activated diseases, a watch must be kept for skin intolerance to the light screening active principle itself or to some component of the base. Almost any substance may occasionally cause contact eczema, but some are safer than others. Of the above list, tannic acid is the most innocuous, followed by salol, sodium *p* aminobenzoate, pyribenzamine, and quinine.

Sodium *p* aminobenzoate should not be used if there has previously been sensitisation to sulphonamides or benzocaine.

Yellow soft paraffin is an effective screen when added to creams in proportions of 50% or more, but its occlusive and "heating" properties may cause discomfort in proportions of 25% and less it does not screen but, on the contrary, has an intensifying effect in the sun's spectral range.

The type of base used has a marked influence on the efficacy of light screening agents. The vanishing cream type of base is both effective and of good cosmetic quality.

In the more unusual cases of sensitisation to the violet blue region of the spectrum, these substances are ineffective and recourse must be had to physical screens but these are only partially effective.

We wish to thank Mr N K Harrison, of the Photographic Department, St Bartholomew's Hospital, and Miss J Todham, pharmacist to St John's Hospital for Diseases of the Skin, for assistance in the preparation of this paper and Messrs Ilford Ltd for producing the spectrographs.

AMETHONIUM IODIDE IN MUSCULAR HYPERTONUS

A A GUILD

B.A. Camb, M.B. Edin., M.R.C.P., M.R.C.P.E.
 CLINICAL TUTOR AND SENIOR MEDICAL REGISTRAR, WESTERN
 GENERAL HOSPITAL, EDINBURGH

view of reports (Organe et al 1949, Organe 1949) the apparently satisfactory and safe use of decamethonium iodide (C10) as a relaxant in surgery, it seemed desirable to see whether it would prove beneficial in muscular hypertonus.

MATERIAL AND METHODS

The following criteria were deemed necessary in selecting cases suitable for trial

- 1) The cases should so far as possible, be of hypertonus out any sensory or cerebellar lesion
- 2) The patients should be reasonably co-operative and intelligent. Preferably they should not show severe degrees of paresis, because muscular power is required for the performance of objective tests

Up to now I have only been able to find seven cases which fulfilled the criteria satisfactorily. Two cases of overlying hemiplegia due to cerebral thrombosis, one of quadriplegia and one of paraplegia caused by laminated sclerosis, and three cases of parkinsonism. The effects of C10 on three healthy volunteers have also been assessed.

Theoretically, in the absence of sensory or of cerebellar defects and of insuperable mental obstacles, when hypertonus is reduced, performance may be expected to improve, provided that muscular power is not also seriously diminished. This applies both to coarse and fine movements. Since the ordinary tests of performance and co-ordination used in clinical neurology can only be used roughly, the following additional tests of performance were applied

- 1) Using a "cyclometer" fixed to a firm base board, such as is sometimes used in making blood counts. The number of times the patient could depress the lever in 15 sec was noted. Results were read automatically from the gauge, which was hidden from the patient, faulty strokes, which did not cause registration on the meter, were automatically excluded.
- 2) The time taken by the patient to pick up twenty medical pegs from a smooth surface, and to insert them into holes drilled in a base board, was noted.
- 3) Where knitting was possible the number of stitches knitted per minute was counted. This test was only used if, because the other patients either did not knit or were too weak to knit.
- 4) In the lower limbs performance was judged by noting the number of times in 15 sec that the foot could be alternately flexed and extended, care being taken to ensure that movements were made through a fixed range, those of greater amplitude being discarded from the total count. By noting the number of times in 15 sec that the heel was applied to the opposite knee and returned to the heel the leg being fully extended at the completion of each movement.

In the performance tests not merely the speed of performance but also its smoothness was observed. In the peg test and the foot test, a test was performed five times consecutively at any one time of day, and the mean was determined. Because of the time required for the knitting and peg tests these could only be used once at each time of testing. Muscular power was tested by a simple apparatus consisting of a long capillary U tube (bore 1 mm), with the walls, filled with mercury to a third of the length of the limbs. One limb was bent through a right angle at the top, and connected by an airtight rubber joint to a further length of thick walled capillary tubing of

equal bore ending in a rubber hand bulb, also attached by an airtight joint. The U tube was attached to a back board mounted on a firm base. The patient squeezed the hand bulb (the paretic hand being used in hemiplegia), the same type of grip being always used by any one patient. The height to which the mercury rose in the opposite limb of the U tube was read on a scale mounted on the back board. The patient was not allowed to see the result. It will be readily understood that for any one patient a uniform type of grip was essential, because quite different power may be exerted by some people with different forms of grasp.

The measurement of tonus presented a major difficulty. A satisfactory method of measuring tonus objectively has not yet been evolved. In these investigations the apparatus designed by Hartbridge (West 1932) was used, in addition to ordinary clinical assessment.

In all cases the patient was given an initial training in the performance of the tests, and the effect of C10 was never investigated until improvement in performance from practice had ceased. Base line performance tests were made additionally before the injection of C10.

DOSAGE AND METHOD OF ADMINISTRATION

Intravenous C10 was given in doses of 2 mg and 3 mg to the three healthy volunteers. In the patients the dosage and route of administration had to be reached by trial and error. It was clear from the initial experiments on volunteers that intravenous administration was likely to be of no value to the patients. It was found that there was little to choose between the intramuscular and the subcutaneous routes. Effects were noted earlier, and lasted a shorter time, when C10 was given intramuscularly. The dose ultimately used was 1.5-2.5 mg. It may be objected that these are small doses compared with those used for relaxation in surgery. However, it was found that with more than 2.5 mg the side effects were too severe for C10 to be of any use to hypertonic patients.

SIDE EFFECTS

When C10 was given intravenously, a feeling of stiffness in the legs and of constriction in the chest developed almost immediately. These sensations passed off in one or two minutes. The feeling of constriction was unpleasant and alarming. The onset of these symptoms was quickly followed by a feeling of facial flushing (the flush being obvious to observers), "tightness" in the forehead, slight headache, ptosis, diplopia, and inability to focus, with consequent blurring of vision. These effects lasted for variable periods: the ocular symptoms for up to five minutes, ptosis for ten or fifteen minutes, and headache for up to thirty or forty minutes. One volunteer had the impression that he could not locate his limbs properly in space, and performance of the finger nose and heel knee tests (after muscular power had been sufficiently restored) was faulty for up to ten minutes after injection. A feeling of slight drowsiness was noted about ten minutes after injection, and lasted for about half an hour. Thirty minutes after injection, walking was still somewhat unsteady.

In the patients with subcutaneous or intramuscular injections sensations were correspondingly less. But all the patients complained of facial flushing, tightness in the forehead, dull headache and sometimes dizziness. Four patients complained of diplopia, all had slight blurring of vision with doses of 1.5 mg or more, and all developed ptosis. One patient complained of dysphagia after 2.25 mg intramuscularly. Blurring of vision lasted for only five or ten minutes, but headache and tightness of the forehead remained from forty to eighty minutes after injection. Ptosis lasted from fifteen to forty five minutes.

Fig 1—Effect of intravenous C10 3 mg on a healthy person

EXPERIMENTS ON HEALTHY VOLUNTEERS

C10 was given to the three healthy volunteers in doses of 2 mg and 3 mg, 90–120 sec being taken for the injection. Observations were made on muscular power (hand grip), on performance, by the "cyclometer" in two instances, and in the third by noting the number of letters type written and errors made on typewriting a standard sentence repeatedly in unit time, this volunteer being a touch typist, and on vital capacity. A representative result for the larger dose is shown in fig 1. The results were on the whole similar to those obtained by Organe et al. (1949), although in two of the three cases there seemed to be a close relationship between the reduction in power and the diminution in vital capacity. Organe et al found reduction in hand strength much greater than diminution in vital capacity. Recovery was rapid in all three volunteers, and apparently quicker than that reported by Organe et al. C5 (pentamethonium iodide) was not administered in any instance. Conceivably, measurement of tidal air, rather than vital capacity, would have been of more practical value. No significant effects on pulse rate or blood pressure were noted.

EXPERIMENTS ON PATIENTS

In five of the seven patients—one case of hemiplegia, one of disseminated sclerosis with quadriplegia, and all

Fig 2—Effects of C10 and of tincture of stramonium in parkinsonism: verticals show range of effects after C10 from initial readings indicated by plotting points

three cases of parkinsonism—either no performance was noted, or actual deterioration after doses of C10 sufficient to produce (20–30%) reduction in tonus and the side-effects mentioned above. In the parkinsonian cases the fall in C10 contrasted notably with the therapeutic success of stramonium. The results in one case are shown in fig 2.

One case of hemiplegia of recent onset showed improvement in performance and power amounting to over 30% after the administration of only 1.5 mg C10 subcutaneously. It is thought that power increased because relaxation of hypertonus permitted an effective gripping of the hand bulb. The experiment was repeated two days later with almost identical results, but, when it was again performed after an interval of four weeks with the same, and larger, doses of C10 no improvement in performance was found. During this period the patient had improved very much clinically and had been receiving physiotherapy.

The other patient in whom improved performance was noted was a female, aged 32, with paraplegia due to disseminated sclerosis. The effects of C10 2.25 mg are shown in fig 3, although the graph does not indicate the smoother manner in which actions were performed at the time of greatest relaxation. Similar results were obtained two days later with the same dose. Larger doses were not used, because complaints of

Fig 3—Effect of intramuscular C10 in paraplegia due to disseminated sclerosis

diplopia, inability to focus, and giddiness followed the administration of 2.25 mg. After a course of Fraenkel exercises performance was significantly better than that found at the point of greatest improvement after injection of C10.

Parallel control experiments with a therapeutically inert substance could not be undertaken, because of the severe side effects of C10.

CONCLUSIONS

In five of the seven cases performance either did not improve or actually deteriorated after the administration of C10. In the two remaining cases the improvement in performance (in one case temporary only), although significant, was not dramatic, and beneficial results were transitory. Unpleasant side effects largely of the advantages of better performance. More pronounced action might be obtained by the use of some suspending base.

My sincere gratitude is due to Dr W. I. Card for allowing me to make these studies on patients under his care, for much help and encouragement in the preparation of this paper, also to Dr J. M. G. Wilson and Dr M. J. Riddell for assistance. My thanks are also due to Messrs. Burroughs Wellcome and Messrs. Allen & Hanburys for supplies of C10 and C5.

TURE OF THE PREGNANT UTERUS BY EXTERNAL VIOLENCE

MARY ELIAS
M.R.C.S.

USE SURGEON, KING EDWARD VII HOSPITAL, WINDSOR

RUPTURE of the pregnant uterus by external violence. I have found only three cases published in the literature.

Lee (1904) reported a case in a woman, aged 40, who in the 8th month of her fourteenth pregnancy fell through a wooden stair the body falling until the protuberant abdomen arrested by a narrow opening. She was admitted to hospital on the day after the injury, with severe abdominal pain and vaginal bleeding. The abdomen was tense but not hard, and palpation revealed a mass high up near the umbilicus. Conservative measures were adopted at first, but the patient's condition deteriorated 28 hours later when operation there was blood in the peritoneal cavity, and immediately beneath the incision, the placenta and membranes, complete and containing the foetus, were found. A large area was found in the posterior wall of the fundus of the uterus, and subtotal hysterectomy was done. Convalescence was complicated by intestinal fistulae and a pelvic abscess; the patient eventually recovered.

Evans (1919) reported a case in a previously healthy primipara, aged 22, 21 weeks pregnant, who, while standing on a platform, suddenly felt faint and fell forwards on to the rails. Examination revealed only minor injuries, and although the patient complained of hypogastric pain, abdominal examination revealed an apparently normal 20-week pregnancy. After 5 hours the hypogastric pain had increased, a watery vaginal discharge was noticed, and the patient's condition began to deteriorate. At operation 2 days after the accident hæmoperitoneum was found and the unruptured uterus was lying free near the spleen. The uterus was contracted and had an oblique laceration 3 in. long on its anterior wall, apparently through the placental site. The uterus was sutured with catgut in two layers and the abdomen closed. The patient made an uninterrupted recovery.

Hosking (1923) reported a case in a healthy woman, aged 35, mother of six children. She was injured by the overturning of a motor-car being struck a violent blow over the right side of the abdomen. She was at the time 6 months pregnant. She complained of right-sided abdominal pain and had some vaginal bleeding. She made a good recovery, remaining well until the 16th day after the accident when feeble labour pains began, and her temperature rose to 101°F. Operation was performed on the 18th day after the accident after an attempt to deliver the child, when a completely detached placenta was moved per vaginam. At operation a macerated foetus was found and completely extruded, except for one leg through a rent in the right side of the uterus. The foetus had become adherent to the bowel and omentum, it was easily moved after division of the limiting adhesions. Blood-clot led the right kidney region. The uterine tear extended from above the external os in front of the right broad ligament. The patient's condition was so serious that hysterectomy was out of the question. The blood-clot was removed from the peritoneal cavity; some adhesions were freed from the fundus and the uterus contracted fairly firmly. A drain was inserted into the right lumbar region, and a long strip of gauze was introduced through the rent into the uterus then in front of the broad ligament and behind it into the pouch of Douglas. It was brought up to the abdominal wall, and the wound was partly closed leaving a free opening in the lower end. Withdrawal of the gauze packing. The patient made steady progress and was up and about a month later.

The following case is reported not only because of its rarity but also because of the unusual injury suffered by the foetus.

CASE RECORD

A primigravida, aged 23, 34 weeks pregnant, was admitted to hospital on Dec. 19, 1948. Half an hour previously she had been involved in an accident on the river. She had been standing on the deck of a motor launch approaching a closed bridge. She had been crushed between the bridge and the gate and the roof of the cabin of the boat. Her only complaint had been of feeling shaken. She had had no

abdominal pain and had been unaware of any abdominal injury.

On examination a laceration of the abdominal wall was found extending from the left iliac fossa to the right anterior iliac spine and as deep as the sheath of the rectus abdominis. There was moderate shock, the pulse rate was 90 and the blood pressure 98/68. On palpation of the abdomen there was no true rigidity but some guarding in the lower abdomen, particularly in the right iliac fossa, which was extremely tender. On the left side the buttocks and back of the foetus could be easily felt, but no foetal heart sounds were heard. Shifting dullness was present and the fundus of the uterus was palpable at the level of the umbilicus. Rupture of the pregnant uterus was diagnosed. Signs of intraperitoneal hæmorrhage rapidly ensued, the pulse rate increasing, the blood pressure falling to 70/50 half an hour later, and the extremities becoming cold and the face blanched.

Initial Treatment.—The patient vomited once after a dose of morphine gr $\frac{1}{4}$. A pint of plasma was given and subsequently three pints of group O Rh negative blood into both internal saphenous veins. The patient's condition steadily improved in the next 3 hours, the blood pressure rising to 100/70 and the pulse rate falling to 120.

Operation.—After premedication with morphine gr $\frac{1}{4}$ and atropine gr $\frac{1}{100}$, anaesthesia was induced with nitrous oxide and oxygen and maintained with ether. The laceration of the abdominal wall was cleaned and packed with a swab of cetrimide. A midline incision was rapidly made and the peritoneal cavity found to contain about three pints of blood and clot. The foetus with the placenta was lying free in the peritoneal cavity on the left side. The uterus was completely torn across at the junction of the upper and lower segments, the tear extending into the broad ligaments on each side. The fundus of the uterus remained attached only by the fallopian tubes and the ovarian ligaments. Both uterine arteries had been divided on the right side 2 in. of artery had been laid bare, but the bleeding had largely stopped. The foetus and placenta were removed, the peritoneal cavity emptied as far as possible of blood and clot with a sucker. The fundus of the uterus was excised with the fallopian tubes, both ovaries being preserved by division of the ovarian ligaments on each side. After ligation of the uterine arteries the lower segment of the uterus was repaired with catgut in three layers and the stump of the uterus covered with peritoneum. Bleeding from the lower segment was arrested by suturing, and the abdominal incision was closed without drainage. The transverse laceration was next dealt with, the edges and lacerated fat excised, the skin sutured, and two small corrugated rubber drains inserted at each extremity.

As soon as the bleeding was arrested the patient's condition improved, blood transfusion being continued throughout the operation.

Postoperative Course.—On the patient's return to the ward her blood pressure was 130/80 and her pulse rate 100. Penicillin 50,000 units four hourly was given for five days together with sulphadiazine ('Sulphamezathine') 1 g four hourly to a total of 20 g. She made an excellent recovery and at no time did her condition give rise to anxiety. Radiography of the pelvis and spine showed no bony injury. A large bruise developed at the level of the fourth lumbar spine, the site of injury to the back in the accident. She was discharged from hospital in good condition three weeks after operation.

Fatal Injury.—The same severe external injury which had completely ruptured the uterus was also responsible for a fracture dislocation of the cervical spine of the foetus (see figure). Radiography showed that the body of the fifth cervical vertebra had been fractured and fragmented. A limited examination of the cervical region of the foetus revealed an extensive hæmatoma surrounding the spinal cord from the

Radiogram of foetus showing fracture dislocation of cervical spine

level of the second to the seventh cervical vertebra. The cord was severed at the level of the fifth cervical vertebra.

It appears that the lower segment of the uterus, and the neck of the fetus, were crushed between the lock gate and the promontory of the patient's sacrum, which was held against the cabin roof.

My thanks are due to Mr R. Vaughan Payne for permission to publish this case.

Medical Societies

ASSOCIATION OF CLINICAL PATHOLOGISTS

THE 44th scientific meeting was held at Leeds from July 20 to 22. Dr NORAH SCHUSTER, in a presidential address entitled *Nec Mors Silet*, spoke of the increasing demands made on pathologists who undertook necropsies, today they must pay attention to parts of anatomy which 25 years ago they could safely ignore. It was comforting to know that at the age of 80 Leonardo da Vinci was to be seen passing through the streets of Milan on his way to the medical school to refresh his memory on points of anatomy. A full medical and occupational history was essential for the pathologist at the time of the necropsy.

Allergic Diseases of Blood-vessels

Dr G. DISCOMBE (London) said that in polyarteritis nodosa biopsy was sometimes negative. Lesions might heal and, if in the kidney, could produce an essential hypertension, the changes of which might almost obliterate those of polyarteritis nodosa. Eosinophilia, though common and usually demonstrable by direct counts during the active phase, was not an essential part of the syndrome.

Dr W. PAGEL (London) said that subendothelial swelling due to permeation of fluid seemed to be followed by exudation of fibrinogen with subsequent necrosis, mostly eccentric, of the vessel wall, a breach in which became plugged with fibrin. Fibrin was deposited, too, both inside and outside the necrotic wall. He preferred to reserve the term "fibrinoid" for changes which failed to show the staining affinities of fibrin, and which sometimes occurred in positions which made it unlikely that one was dealing with fibrin which had lost its staining affinities. In his opinion the differences between polyarteritis nodosa and the "pararheumatic" diseases, including lupus erythematosus disseminatus, dermatomyositis, and temporal arteritis, concerned the natural history of the disease and the preferential site and distribution of the basic change rather than the basic histology, which appeared to be identical. In polyarteritis nodosa extramural foci involved the collagen fibres and were indistinguishable from the acute infiltrative changes in rheumatic fever, lupus erythematosus disseminatus, and dermatomyositis. In some instances healed polyarteritis nodosa seemed to be the basis of an eosinophil-cell alveolitis (Loeffler's syndrome) associated with exfoliative dermatitis and asthma (in one case terminated by cerebral haemorrhage). While in these cases the arterial changes appeared to be burnt out, the eosinophilia was active, so that it was not necessarily to be interpreted as a cellular reaction to local arterial necrosis. Intradermal injection of heat-killed streptococci in healthy persons and in rheumatic and other patients who had volunteered had established the significance of bacterial antigens in the reproduction of the changes characteristic of polyarteritis nodosa. Both the histological and experimental evidence supported the view that polyarteritis nodosa and the related diseases were an expression of the hyperergic response to any aetiological factor, including bacterial (notably streptococcal) antigen.

Dr I. RANNIE (Newcastle upon Tyne) said that, for biopsy, muscle was the material of choice, a tender area should be chosen for excision, and a negative report should not be issued until serial sections have been studied.

Prof T. CRAWFORD (London), said that the types of procedure had led to the production in animals closely resembling those of polyarteritis in man. The first, introduced by German about 1930 and used extensively by Rich and in the U.S.A., consisted in administration of protein to a suitable animal such as the rabbit. The second, described in this country by Wilson and depended on the production of hypertension by a procedure such as the clipping of a renal artery. The interpretation of these experiments which Crawford favoured was that the first procedure led to tissue antigen-antibody reaction characterised by necrosis and fibrin deposition in the vessel walls and a reaction around the injured area, whereas with the second procedure sudden elevation of blood-pressure caused damage to the less well supported arteries and again led to necrosis and fibrin deposition in the vessel wall, with a secondary cellular response as in the first lesion. The first procedures seemed to constitute a closer parallel to the conditions of the human disease.

Other Subjects

Dr G. B. S. ROBERTS (Glasgow) reported *findings in the prodromal stage of measles*.

Koplik's spots developed twelve days after the administration of convalescent measles serum and the child died from fulminating pneumococcal meningitis which occurred before the appearance of the rash. The lymphoid tissue throughout the body showed hyperplasia of the germinal centres with formation of large multinucleate giant cells of the Warthin-Finkeldey type. A second case was mentioned, in which a cervical lymph node, removed at operation, was found to show typical Warthin-Finkeldey giant cells. Although this child had been exposed, a clinical attack of measles did not develop, so it seemed possible that infection could produce histological changes without any clinical manifestation of the disease. Giant cells found in the lung of the fatal case contained large numbers of acidophilic intracytoplasmic inclusion bodies varying greatly in size and shape.

An attempt to communicate the disease to rabbits by intravenous inoculation of citrated blood taken from patients on the day of appearance of the rash was unsuccessful.

Dr I. FRIEDMANN (London) reported that the *Papanicolaou method of diagnosis*, despite limitations, was of real value in the diagnosis of tumours of the nose and throat.

Dr T. B. MAGATH (Rochester, Minnesota) discussed various phases of the *prothrombin* problem, and described a convenient one stage technique.

Plasma, serum, and platelet extracts possessed activity concerned with the conversion of prothrombin to thrombin. Since zymon plasma produced a conversion deficiency which differed from that produced by ageing or by ammonia, it appeared that there was more than one conversion factor. A apparently low prothrombin value might be caused by a lack of one or more conversion factors. The thromboplastic effect of platelets was due partly to an associated prothrombin conversion factor, while complement had been shown to possess properties very like some conversion factors in plasma. Several experiments were described and critical values of dicoumarol therapy given.

Dr R. AIDIN and Dr G. H. TOVEY (Bristol) gave an account of *sixth day disease*, a syndrome consisting of prematurity, jaundice, and kernicterus, with death usually about the sixth day of life. In their experience kernicterus was most commonly found in this condition. 25 examples, unassociated with haemolytic disease, having been found in a series of necropsies on 144 premature infants. While the naked eye appearance was indistinguishable from the kernicterus found in haemolytic disease, clinical, necropsy, histological, and serological studies failed to support a diagnosis of haemolytic disease. Neither was there any evidence of sepsis or syphilis.

Dr R. W. FAIRBROTHER (Manchester) dealt with *clearance of Staphylococcus pyogenes from the nose*. The application of penicillin cream had proved of value, but the clearance was usually only temporary, for staphylococci tended to recur a few weeks after the cessation of treatment, in spite of repeated courses of the cream. In some instances the fresh organisms were of a type different from that of the original staphylococci.

Vice-Marshal T C St C MORTON (Wendover) read the carrier rate of amebiasis in Britain. Of R A F apprentices, 16 had been found to carry *amebiasis* cysts, and 3 cases of amebic ery, 1 fatal, had been encountered in R A F and who had never left Britain. Of these, 2 had contact with patients suffering from dysentery infected overseas.

T B MAGATH believed that the incidence of malaria in the United States was of a similar order, namely, about 10-20%, although textbooks often give a carrier-rate of 10%. It took many years of experience to become proficient in recognising pathogenic malarial parasites and he believed that iron hæmatoxylin was the stain of choice.

G S WILSON (London), describing the survey made in England and Wales during 1943-45 on the distribution and frequency of non-pulmonary tuberculosis caused by *Mycobacterium tuberculosis*, took the opportunity of thanking the 149 pathologists who had collected specimens. In England and Wales 994 patients had been examined, of whom 20.3% belonged to the bovine type. The age distribution according to site of disease was: lungs 27.1, cervical glands 46.5, bones and joints 10.6, genito-urinary system 12.8, miscellaneous 10.6. The proportion of bovine-type strains was highest in the first quinquennium of life, and higher among females than males. It was calculated that in England and Wales during 1944 about 24% of all cases of non-pulmonary tuberculosis were of bovine origin and that 0 to 1400 persons died of milk-borne tuberculosis. Dr Wilson drew attention to the high proportion of mistaken diagnoses in cervical adenitis and suggested that further work was required to distinguish the tuberculous from other forms of the disease.

Dr G STEWART SMITH (Exeter) spoke on the problem of non-pulmonary tuberculosis as seen in an urban and rural community in the south-west.

Dr A J RHODES (Toronto) gave an account of the demography of the Coxsackie virus and of a recent epidemic in Dufferin county, in which the viruses both poliomyelitis and of the Coxsackie infection appeared to take part, it appeared that the two viruses possessed similar epidemiology. Dr F O MACCALLUM (Colindale) described the results of investigations of material sent to the Virus Reference Laboratory, and discussed current problems of diagnosis.

Dr J B FOOTE (London) discussed the interpretation of blood-cholesterol estimations, favouring the method of colorimetry because of its simplicity, reproducibility, and speed. However, in a series of 35 male and 17 female medical students, he and Dr Mervale had found the normal range to be 150 to 350 mg per 100 ml. The method had the disadvantage of not separating free cholesterol from its esters, and rate of colour production and intensity of colour were not the same for free and ester cholesterol. Nevertheless, by careful attention to technique, the errors tended to cancel out. Despite the altered normal range they confirmed the usefulness of cholesterol estimation in the diagnosis and control of treatment of 22 cases of myxoedema, but in 49 examples of thyrotoxicosis the overlap with a normal range was so great (8%) that the use of serum-cholesterol estimations in its diagnosis was precluded. 30 cases of hepatitis registered at the Westminster Hospital showed a wide overlap and 90% overlap with a normal range.

Dr P G WALKER and Mr R D WILKINS (London) compared the polarographic serum waves with the colorimetric and formol-stable serum acid phosphatases in a series of cases diagnosed clinically as malignant disease of the prostate. 55% had abnormal polarographic waves and 52% abnormal phosphatase values, but these did not necessarily coincide, for while in 25% both values were high and in 75% one or other was above normal, both values were within the normal range in 25% of cases.

Prof C H GRAY (London) made observations on acute porphyria, 8 examples of which had illustrated the great variation in the clinical picture and had supported the view that this condition was wholly different from congenital light-sensitive porphyria. In all probability, said, congenital porphyria was a genetically deter-

mined enzyme abnormality, probably localised in the bone marrow, leading to production of type I porphyrins in excess during erythropoiesis. In acute porphyria there might be an excessive production of mono-pyrrolic porphyrin precursors, possibly in sites of porphyrin synthesis other than the bone marrow. The clinical condition could be brought about by a direct action of the porphyrins on the central nervous system, or by primary changes in the central nervous system resulting in the excessive production of porphyrin precursors or by the direct action of the porphyrin precursors themselves on the central nervous system.

Dr E M DARMADY, Dr J HARKNESS, and Dr A RICHARDSON JONES (Portsmouth) drew attention to the fact that oliguria and anuria might follow a large number of precipitating agents, over 60 of which had already been described. The majority of cases, however, ran similar courses and could be divided into three phases.

The first was one of precipitation, frequently taking the form of shock in which there was oliguria and hæmoconcentration. This was followed by the anuric or oliguric phase in which there was a rapid rise in blood urea, a fall in sodium and chlorides, and a rise in potassium, with its danger of acute cardiac failure. It was important to restrict fluids in this second stage. The two methods of controlling accumulation of metabolites, either by dialysis, as a temporary measure, or by a high fat and high carbohydrate diet, were reviewed.

In the third, or diuretic phase, the evening output might rise very suddenly, often with a serious fall in potassium. Faulty hydration was, in their opinion, the important aspect of the disease.

Dr C J YOUNG (Bradford), in considering the agranulocytosis of glandular fever, expressed the opinion that this was a diagnosis which was commonly missed. When looked for, 3 examples had been seen in a period of just over two years, one of which yielded new information on the nature of the condition. In this case the marrow was found to be normal, but the granulopenia persisted in the blood and was still present 2½ years later. The condition was liable to be confused with drug agranulocytosis but there were four features which helped to distinguish it, although none were specific: these were the Paul-Bunnell test, the constant presence of a few polymorphs in the blood, the normal bone-marrow, and the absence of fatalities. Dr Young suggested that agranulocytosis was due to the unduly rapid removal of polymorphs from the blood, and not to a failure to produce them in the marrow. He recommended that glandular fever should be looked for in agranulocytosis which might be due to other causes. When granulopenia was due to this condition the prognosis was good, and the patient need not be deprived of a suspected drug, if it was likely to help him. Bacterial invasion could, however, occur.

Dr OSCAR B HUNTER, jun (Washington, D C) referred to reports that carcinoma in situ in the cervix might develop into invasive carcinoma. However, proof that carcinoma in situ was actually the precursor of invasive carcinoma was presumptive. Biopsies might miss an invasive carcinoma, whereas in attempting to examine the cervix adequately conisation sections might completely destroy the lesion.

Other evidences of the relationships existed, in that the statistical incidence of cases of the two lesions were approximately the same. Carcinoma in situ averaged round 35 years of age, whereas invasive carcinoma was 45 years. From experience of 20 cases of clinically occult cervical lesions discovered by positive cytological examination, he had discovered extremely early evidence of invasion in what was otherwise only carcinoma in situ. This evidence had been found after serial sections of the cervixes.

Dr O MERSKEY (Oxford) described laboratory findings in cases of hæmophilia.

He advised using both the techniques of Lee and White and of Dale and Laidlaw for a study of the coagulation time. The former had proved more consistent, though the latter, because it was made on capillary blood, was valuable, especially in children. Though usually greatly prolonged, the coagulation time in undoubted instances of hæmophilia might be consistently normal whilst in others it was only slightly prolonged. He spoke too of the defect of consumption of prothrombin during coagulation, a defect which was marked

when the coagulation time was greatly prolonged. In fact the serum from either venous or capillary blood appeared to contain even more prothrombin than the original plasma. In instances where the coagulation time was normal the defect was less, but usually was demonstrable on serum derived from venous, but not capillary, blood. The addition of a small proportion of normal blood to known hæmophilic blood greatly improved the coagulation defects of the latter by reason of its making available some of the "antihæmophilic globulin."

There appeared to be all grades of the hæmophilic defect as measured by the coagulation-time, the degree of the prothrombin consumption defect, and the absence or unavailability of antihæmophilic globulin. The degree of the defect in any individual remained fairly constant from year to year and seemed to breed true in any particular family even over a number of generations.

Dr J. V. DACIE (London) referred to a number of discrepancies concerning the behaviour in vitro of cold hæmolysins in cases of cold hæmoglobinuria. He concluded that as real differences existed between the behaviour in vitro of cold hæmolysins no test should be regarded as negative unless it had been carried out with serum acidified within the pH range 6.5-7.5 and a further tube set up in which an equal volume of fresh normal serum had been added to the patient's serum, so as to provide an adequate concentration of complement. The patient's serum should never be heated, and fresh serum must be present in both the cold and the warm phases.

Speakers at the dinner of the association included Prof MATTHEW STEWART and Dr ROBERT A. MOORE, professor of pathology at the Washington University of St. Louis, Missouri.

New Inventions

SIMPLE "BOOSTER" FOR OBSTETRIC GAS-AIR APPARATUS

THE gas-air mixture in obstetric analgesia machines is set to such a degree of safety that any further dilution with air renders it ineffective—a practical application of this fact being the necessity of ensuring that the mask

Fig 1—Site of booster

accurately fits the patient's face. It is not generally appreciated, however, that, in the intervals between uterine contractions, when the apparatus is not in use, air diffuses via the mask and finger-hole into the delivery tube and dilutes the nitrous oxide to such an extent that it takes several breaths before the mixture is restored to full strength the next time the mask is applied. Hence the effects of analgesia are delayed and relief is not so complete as the legal mixture is capable of producing.

The device illustrated in fig 1 is designed to avoid this disadvantage. It consists of a facepiece mount placed between the mask and the delivery-tube and containing a non-return spring valve (fig 2) which traps the gas-air mixture and prevents dilution by diffusion. Thus, once the machine has been used during a contraction the delivery-tube will thereafter retain a full strength mixture, so that each time the mother applies the mask she will inhale this mixture from the very first breath.

Three of these face mounts have been in constant use in the obstetric wards of King's College Hospital for the past ten months and the sisters report a remarkable improvement in the efficacy of gas-air analgesia since their introduction. They are quite robust and have

Fig 2—Details of valves

stood up to the usual buffeting without any impairment of the valves.

The device has been made by Medical Pneumatics Ltd. of 28, Teyler Street, London, W.1, and I wish to thank Mr H. A. Talley of that firm for ensuring that the non-return valve does not add appreciably to the weight of the facepiece or make it clumsy to hold.

A. H. GALLEY
M.B. Lond., F.F.A.R.C.S.
Anaesthetist to King's College
Hospital, London

Reviews of Books

Textbook of Gynaecology (3rd ed. London W.B. Saunders 1950 Pp 477 24s.)—Mr J. H. Peel Heinemann 1950 Pp 477 24s.)—Mr J. H. Peel up to date his well known textbook, which first appeared in 1943, as a revision of Forsdike's work. No attempt has been made to cram into a text intended for students every phase of gynaecological practice (indeed he seems to be aimed rather at excising those methods which have not stood the test of time), but the treatment sections have been thoroughly revised, and the illustrations, always good, have been further enriched by a series of new photomicrographs.

Medical Jurisprudence and Toxicology (9th ed. Edinburgh E. & S. Livingstone 1950 Pp 755 36s.)—This famous textbook has been given a new and contemporary balance. Prof John Glaister has included new material on the liability of hospitals and nursing homes, the medical aspects of artificial insemination, the National Health Service, National Insurance, and many other topics. War gas has been omitted, and the effects of blast relegated, prematurely to the end of the chapter on wounds. The effects of the atomic bomb have made their first appearance. New substances added in the section on toxicology include DDT, amphetamine sulphate, beryllium, and radioactive substances.

A New Dictionary of Chemistry (2nd ed. London Longmans, Green 1949 Pp 580 60s.)—This dictionary, edited by Stephen Miall and L. Mackenzie Miall, is designed as a 'compact work of reference,' and such it is. It contains some 5500 references, it is smaller in size than most comparable dictionaries. Its value lies in the fact that it is largely an initial reference book, but it is altogether free from errors. Thus it was not Madame Curie who, with Joliot discovered artificial radioactivity, dehydrogenases are not usually considered reducing enzymes. Some may feel that in future editions it would be best to remove the biographies of living persons, especially as they tend to become out of date rapidly. In their place, more references to original work on individual subjects would usefully be given.

THE LANCET

LONDON SATURDAY, AUGUST 12, 1950

Tobacco and Lung Cancer

ONE of the first questions likely to be asked in a discussion of the aetiology of cancer of the lung is whether there has been any real increase in the disease since, say, the beginning of this century. The answer is that we do not know, because there are no figures either here or in any other country on which an actual death rate from intrathoracic cancer of forty years ago can be compared with that of today. PASSEY and HOLMES¹ analysed the available post-mortem records of British teaching hospitals up to the end of 1928 and could find no evidence of any increase, though their survey covered a period in which there had apparently been a dramatic increase in other European countries.² Professor DUNGAL, who discusses the low incidence in Iceland on p. 245, assumes that there has been a real increase in Britain and the United States, but this cannot yet be proved. However, in 1947, on the basis of the Registrar-General's figures, KENNAWAY and KENNAWAY³ assessed the apparent increase in this country (on which all authorities agree) and concluded that it was probably real—at least in part.

Three known facts about lung cancer must be of biological significance: its high incidence among Iceland, cobalt, and pitch-blende miners in Schneeberg (Saxony) and Joachimsthal (Czechoslovakia), its late appearance in sufferers from asbestosis, and its preference for males. Of these three, only the sex-distribution is likely to be a direct help in unravelling the cause of lung cancer in the general population, though the relation between fibrotic lung disease and the subsequent development of cancer has parallels in other organs. ORR's⁴ experiments have shown that stromal changes may alter the vascular conditions in the tissues, with the result that the parenchymatous cells which can best withstand the altered conditions may increase at the expense of the rest and thus become malignant cells. The fact that the incidence of bronchogenic carcinoma is five times as great in women as in men⁵ may also be aetiological significant when we come to the possible environmental factors which might explain the apparent increase in lung cancer, tobacco smoking, tarring of the roads, and

inhalation of exhaust fumes from petrol engines suggest themselves at once. There seems to be no experimental or clinical evidence of the carcinogenicity of dust from tarred roads or fumes from motor engines—no one has suggested that there is a special susceptibility to lung cancer in motor drivers or engineers, who must inhale a larger amount of exhaust fumes than most other sections of the community. But tobacco smoking is another matter, and their recent clinical investigation in the U.S.A. has led WYNDER and GRAHAM⁶ to conclude that the "excessive and prolonged use of tobacco, especially cigarettes, seems to be an important factor in the induction of bronchiogenic carcinoma." At the International Cancer Congress⁷ in Paris last month, other American speakers supported their view that the incidence of lung cancer is significantly higher in heavy smokers than in non smokers.

WYNDER and GRAHAM personally interviewed 634 patients in whom cancer of the bronchus had been diagnosed by microscopical examination of tissue obtained at biopsy or of bronchial secretions. The smoking habits of these patients, determined by medical observers and assessed by an arbitrary method over 20 years, were compared with those of three control groups of hospital patients: sufferers from chest diseases other than bronchiogenic cancer, inpatients of the general medical and surgical wards (both of these groups were questioned by non medical observers), and a final group similar to the second but interviewed by physicians. In other words, the smoking habits of the lung cancer group were compared with those of the general hospital population and not with the population as a whole. Some criticisms may be raised. Was the method of diagnosis reliable, and was any attempt made to confirm it at necropsy? Most pathologists in this country would hesitate to affirm that the diagnosis of lung cancer by biopsy is accurate enough for research purposes. Again, do the smoking habits of a hospital population fairly represent those of the whole population? May not patients with chronic chest and other diseases have cut down their smoking because of their chronic ailment? Then, might some other factors that were not investigated have been concerned? No attempt was made to ascertain whether the control groups of patients contained the same proportion of urban and rural dwellers, who might be expected to have different smoking habits. Despite the large scope of this inquiry, it seems therefore that confirmation from other sources is needed.

Professor DUNGAL has reviewed close on two thousand necropsies he and his assistants have done at Reykjavik in 1932-48, and he has found only 12 lung cancers, an incidence of 0.6%. This is, he says, as low an incidence as many European countries had 40-50 years ago, and he relates it to the very moderate consumption of tobacco in Iceland up to the beginning of the late war. Since then smoking has increased rapidly—from under 1½ lb a head in 1940 to nearly 1½ lb in 1947—and DUNGAL foresees a corresponding rise in the incidence of lung cancer 20-25 years hence, on the assumption that a carcinogen will take this time to produce a manifest growth. If his argument is accepted we in this country must expect a rising

incidence of lung cancer for something like 20 years—at least, for there seems to have been a steady increase in tobacco consumption up to 1946, though since then the heavier duty has produced a sharp fall. The following figures, kindly supplied by the Statistics Division of the Board of Trade, give a good rough measure of the tobacco actually smoked in the United Kingdom in the last 25 years.

ANNUAL AMOUNTS OF IMPORTED AND HOME GROWN TOBACCO CLEARED BY CUSTOMS FOR HOME CONSUMPTION OR SUPPLIED DUTY FREE TO SHIPS' STORES, H.M. FORCES OVERSEAS, AND PRISONERS OF WAR

The question whether tobacco contains carcinogenic substances should, one would suppose, be answerable from experimental research. FLORY,⁸ who tested on rabbits' ears the carcinogenicity of tar produced by the destructive distillation of tobacco at 350–700°C, concluded that the tar contained a weak and slowly acting carcinogen. The temperature was not far removed from that which obtains in pipes and cigarettes, but the conditions of the experiment were entirely different from those which would govern the exposure of the bronchial and bronchiolar epithelium to tobacco smoke. Many fruitless attempts to induce bronchial carcinoma by "smoking" laboratory animals in closed chambers have not even been deemed worthy of record. A more significant contribution to the ætiology of this disease may well be the demonstration of benzpyrene in the suspended matter obtained from the air of London, Sheffield, Manchester, Liverpool, Burnley, Bilston, Hull, Bristol, and Leicester.⁹ This hydrocarbon, a constituent of coal tar, is an undoubted and potent carcinogen. Those who inhale the polluted atmosphere of any of these towns may derive a grain of comfort from the fact that "no evidence has been found so far of any formation of benzpyrene by the combustion of tobacco."

Ion-exchange Resins

CLINICIANS are paying more and more attention to changes in the composition of the extracellular fluid of the body¹—the *milieu intérieur* of CLAUDE BÉZARD²—particularly in its content of sodium and potassium. In this they are being aided and abetted by chemists, who are providing them with two new tools, both of which are beginning to be used in hospitals. The first is a diagnostic tool, the photometer, by means of which the concentration of sodium or potassium in serum, urine, or other fluids can be estimated in a few minutes with great accuracy. The second is therapeutic, and comprises the use of substances known as ion exchange resins, which will remove sodium or potassium ions from solution in exchange for other ions.

The ion-exchange or base exchange principle has been applied commercially for many years, a familiar example being the 'Permutit' water softeners. This is a group of insoluble silicates which can absorb various ions and some non-ionisable compounds from solution and hold them in light combination. When even a temporary inundation by sea water on agricultural land for many years is mainly because of silicates in the soil hold on to the sodium ion. Permutit, a synthetic zeolite, is one of these silicates. In a water softener the hard water is brought into contact with permutit which has previously been saturated with salt and is holding sodium ion in loose combination. Permutit has, however, a greater affinity for calcium and magnesium than for sodium, and as the hard water flows through the softener the calcium and magnesium ions are taken up in exchange for sodium and the water becomes soft. This process can be continued indefinitely if the permutit is resaturated with salt from time to time. A similar process has provided the answer to the age-old problem which became acute in the late war—how to make sea-water drinkable. Into a rubber bag which has filled with sea water the ditched airman or a wrecked seaman puts one of his zeolite briquets, crushed up, he shakes the bag well, and very soon can squeeze the bag and obtain potable water from the exit tube.

In 1935 synthetic phenol formaldehyde resins with cation exchange properties began to be developed. Resins were prepared from aromatic amines and formaldehyde which have anion exchange properties.³ In 1944 STEINBERGER⁴ used a cation-exchange resin to remove calcium from the blood, replacing it with sodium ion, and so prevented clotting. SEGAL and his collaborators⁵ used an anion exchange resin to reduce the acidity of various solutions, in particular gastric juice in vitro. They also demonstrated that the resin was virtually nontoxic to rats which ate it by mouth over long periods. SPEARS and PRENTISS⁶ have lately treated 18 cases of peptic ulcer with a cation exchange resin with encouraging results. An approach to the correction of a disturbance in the composition of the body fluids was made in 1944 by MURHEAD and REID⁷ who tried a "resin artificial

1 For a masterly introduction to these changes and the conditions in which they arise see J. L. Gamble's monograph, 'The Anatomy, Physiology and Pathology of the Extracellular Fluid,' Cambridge, Mass., 1949.

y" in the treatment of bilaterally nephrectomized dogs. The dogs were fully heparinized, and arterial blood was circulated through a tube containing a mixture of cation and anion exchange resins, which had been pretreated with a solution of electrolytes in concentrations normally present in the extracellular fluid. The resins can take only a relatively small amount of urea out of solution, but when they are saturated they can be washed free again with the normal pretreatment fluid. In this way urea can be removed from the uræmic animal—admittedly rather slowly—and electrolyte disturbances can be partially corrected. The method will not remove excess water from the body directly, as can be done by peritoneal dialysis or with KOLFF's "artificial kidney," but the direct removal of water from oedematous patients whose renal function is adequate can be achieved by active removal of the sodium ion from the body. Sodium ion exchange resins may turn out to be of considerable clinical value. IRWIN *et al*³ have shown that cation exchange resins given by mouth will bind a large quantity of sodium in the intestine, and a normal person's urinary excretion of sodium can be reduced to less than 0.2 g daily despite an intake of 6.0 g of salt. They also gave the resins by mouth to two patients with cardiac failure and oedema and one patient with nephrosis and peripheral oedema, and in all three the reduction in oedema obtained was greater than with diuretics. Four American groups of workers²⁻¹² have recently reported on their experiences with cation exchange resins. Their results in cardiac oedema have been promising. In this method of treatment the sodium ion is exchanged either for H^+ or NH_4^+ , and acidosis may be induced or aggravated if renal function is inefficient. The possible loss of other ions, particularly potassium and calcium, is another danger that must be borne in mind. Theoretically, at least, this can be avoided by partially saturating the resin beforehand with potassium and calcium. Patients can take the dry granular resin in quantities up to 100 g a day without difficulty, and constipation is seldom troublesome. The preparation is now being obtained in this country. So perhaps before long our patients with hypertension, cirrhosis, or cardiac failure will discard their salt-free diets and eat normal food, leaving it to a resin to remove the sodium from their intestines.

Nutrition in South and East Asia

In these days the newspapers and wireless give all too frequent accounts of the failure of the United Nations to bring men together and to settle their differences of opinion. These failures make it easy to lose confidence in the possibilities of international co-operation and to relapse into a spirit of national chauvinism which we know should be outmoded. It is important therefore to note well the successes of the United Nations, for these are the shoots from which we may expect fresh growth and development. One such success is the Nutrition Committee for South and East Asia, organised by the Food and Agriculture Organisation of the United Nations, whose second

meeting was held at Rangoon last February with Dr JUAN SALCEDO, of the Philippines, in the chair.¹ Delegations attended from Burma, Ceylon, India, Indonesia, Korea,² the Philippine Republic, and Thailand, and there were representatives from France, the United Kingdom, and the United States, as well as from the other U.N. organisations, UNESCO, UNICEF, and WHO.

Rice is, of course, the staple food in South and East Asia, and the committee were much concerned with ways and means to improve both its quantity and its quality. A recommendation of the previous meeting that a thiamine content of 1.5 microgrammes per gramme should be regarded as a minimum standard for milled rice was reaffirmed, but the attainment and enforcement of such a standard is handicapped by the lack of a suitable method of thiamine assay. Two methods (the thiochrome and the microbiological) can be used, but each requires equipment and analytical skill to be found only in a few big centres in Asia. The committee urged the need to discover a more convenient method. Methods of milling and parboiling the grain vary greatly according to local customs and techniques, and so does the new process of "enrichment" by additions of thiamine, riboflavin, and nicotinic acid. Different methods of washing and cooking in the home also affect the loss of nutrients. That the rice grain must lose some nutrients in the processes through which it passes between harvesting and consumption is inevitable, and these losses can only be minimised if detailed studies—some chemical and engineering, others social and economic—are carried out in the mills, warehouses, bazaars, and homes of each of the diverse rice eating areas. The promotion and co-ordination of these studies is an opportunity for an international agency.

Rice diets usually contain too large a proportion of the cereal and are defective in foods rich in proteins, minerals, and vitamins, such as pulses, fish, and vegetables. Milk is seldom taken in sufficient quantities. Recent technological work on the manufacture of "partial milk substitutes" from soya bean and other foods has so far been only on a laboratory scale with small field trials. Joint effort by commercial organisations and governments is necessary if such new food preparations are to be widely distributed. The committee thought that work of this nature should be encouraged, but recommended that in each country attention should be concentrated on sources of food readily available locally.

The British welfare food services and school meals services are prototypes on which others look with a mixture of critical admiration and envy. In rice eating countries, the high infantile and juvenile death-rates and widespread malnutrition among children all point to the need for schemes for providing assistance in the feeding of mothers and children. Unfortunately, these countries have neither the food and money nor the administration needed for developing welfare food services on a scale comparable to our own. Nevertheless, a number of them have been able to start feeding programmes, and in the last two years these have been extending. Much ingenuity is being

2 The Korean delegate came from the department of public health Seoul but is listed as representing Korea.

used in devising cheap meals from foods grown within their own borders, and as experience is gained there should be a corresponding improvement in child health. The committee also discussed the problems of feeding industrial workers, whose numbers are steadily increasing, and plantation labourers. The low standards of health and economic efficiency among these classes can be much improved by communal feeding schemes. In considering nutrition education at various levels, the committee agreed that there is a need for highly qualified nutritional workers able to accept administrative responsibility and to plan new ventures. Such persons will require postgraduate education, both within and outside the region. The methods of teaching the elements of nutrition to nurses, school-teachers, and other people in influential positions were also debated.

F A O has neither the resources nor the finances to carry out big nutritional programmes in individual countries. There is no master "United Nations Nutrition Plan" to feed the peoples of Asia and save them from the ever-present threat of starvation and famine. Perhaps this is just as well, for grandiose

schemes for social betterment readily lead to delusions and disillusionment. F A O is at present an agency for coordinating nutrition work in many countries, and for collecting, sorting, and disseminating the mass of technical information on nutrition. Yet it is this building of a firm foundation of knowledge that is necessary for social development. A nation of agricultural, economic, and political principles and techniques among the peoples of Asia is an essential beginning to the establishment of a stable political structure. In considering the present Asiatic scene, we must remember that war and aggression are old and well known manifestations of human evil, and that present unrests are continuations of long-established tensions. By contrast, the national scientific conferences, with official delegates from many countries, are something new and effective. The fact that such conferences are now held with success, as this report shows, is a sufficient excuse for an optimist to believe that there is a future both for the United Nations Organisation and for the poor rice eaters of Asia.

Annotations

FIRE

"HOUSE on fire" is an accident which everybody expects to watch, never to experience. As a new booklet, prepared by the Interdepartmental Fire Prevention Committee and the Central Office of Information, points out, fire nearly always strikes without warning, and the danger may be recognised too late to avoid disaster. We all think we know the rules for preventing fire in the home, yet probably everyone who reads this little book will find in it one or two things which take him by surprise. Do most of us realise, for example, that it is dangerous (as well as inefficient) to earth a wireless set to a gas pipe? Or that "mains" leads to wireless sets which get warm in use should be open to full length and not coiled or placed inaccessible behind furniture? Or that tubular or panel electric heaters, unless designed for the purpose, should not be covered directly with airing clothes? Or that oily rags or rags soaked in paint are liable to self-ignition? All the accidents against which this little book warns us have happened, and though they are hair-raising, everybody old enough to understand the meaning of the words should read about them.

In this country we are particularly exposed to risks from electricity and gas because heating devices of either kind are nearly always sold without guards, and because in place of the central light and fixed hearth of former days we now have homes draped with festoons of flex or lengths of dangerous rubber tubing, and carry unguarded fires from place to place. Sweden, Denmark, and some other places have already taken precautions against such risks. In Sweden, for instance, no electric fire can be sold which does not bear an "S" mark, meaning that it has been passed as safe by an organisation called SEMKO—"safe" here meaning free from risk as regards thermal injury as well as from electrical hazards. This is a company jointly owned by the United Electrical Power Companies, the United Electrical Industries, and an association for preventing accidents by fire. This company pays no dividends, but is maintained by the small charge made for examining and passing electrical appliances. The charge is so small that it does not affect the market price of the goods

The government requires that all electrical appliances should bear the SEMKO mark, but otherwise does not interfere. The death rate from burns in Sweden is about 10 per million population, compared with our 21. In Denmark use district heating extensively, and also prohibit the sale of unguarded electric fires. English fires exported to Iceland must carry a guard which complies with safety regulations, so we are in the strange position of manufacturing safer fires for Icelanders than for ourselves.

The British Standards Institution has been considering safety specifications for electric fires for over three years. It produced draft specifications nearly a year ago, but has not yet issued a report. Meanwhile, though some of the chief manufacturers have produced satisfactory designs, they are not willing to put them on the market until they see the final specifications of the B.S.I. Electrical manufacturers are the more inclined to hold back because the gas industry has produced no specifications at all. Manufacturers of open fires, however, have recently been considering ways of improving the design of fireguards.

Another approach to fire prevention, and especially prevention of burns, would be by way of fireproof clothing materials, and in particular raised cotton fabrics. These fabrics, it is thought, are probably responsible for a very large proportion of burns in the home. Among the first 1000 admissions to the burns unit at the Birmingham Accident Hospital it was found that 8% of domestic burns were due to clothing catching alight, and 88% of all the deaths from burns were due to this cause. Dr Leonard Colebrook, F.R.S., to whom we are indebted for many of these facts, is at present sending samples of clothing worn at the time of such accidents, for examination by a textile expert. His reports show that among the 32 samples of clothing (from 24 burned persons, so far examined, 20 were of cotton, 7 of viscose rayon, 2 of cotton mixed with viscose rayon, 1 of cotton mixed with wool, and 2 only of wool). The two woollen garments came from people who were also wearing cotton. Some new methods of fireproofing materials have lately been reported from America. If one or more of these should prove suitable in every respect but the cost, Dr Colebrook suggests that, in view of the high cost of burns injuries to the country, there would be a strong case for subsidising the cotton industry to fireproof fabrics sold.

THE RHONDDA FACH SCHEME

this scheme, announced to the press on July 31, pneumoconiosis Research Unit (P R U) of the Medical Research Council is turning its attention to the problem of tuberculous infection in coalminers with pneumoconiosis. In essence the idea is simple but ambitious: to radiograph a complete community of some 30 000 in a mining valley. The non-miners will be examined by a mass miniature radiography unit of the Welsh National Hospital Board, and the miners with full size by the mobile X-ray unit of the P R U. The scheme is being locally controlled by an advisory committee, with Dr Norman Tattersall as chairman and is the blessing of the Ministry of Health. Made possible by co-operation of various medical authorities, the concentration of their work in one limited area, the scheme will be carried out without any increase in the cost of the organisations concerned. Its three main aims are:

To reduce the number of sputum positive tuberculous cases in this one area by means of universal radiography followed by admission of suitable cases to hospital, and by health visiting to instruct the remainder in sputum control.

To study the effect of this reduction of infectivity on the tuberculin sensitivity of school-children and the attack rate of tuberculosis of all forms in the community.

If a considerable reduction of tuberculous infectivity is achieved, to study the attack rate of massive fibrosis among miners already affected by simple pneumoconiosis which is widely believed to be a modified form of tuberculosis.^{1,2}

Several points of interest arise. Mass radiography has hitherto had as its chief objective the diagnosis of tuberculosis at an early stage so that prompt treatment can be provided. Because of the absence of satisfactory evidence that treatment significantly affects the prognosis of these early lesions, it is questionable whether this should have been its main objective. In the Rhondda Fach scheme the therapeutic aim, while not abandoned, has been subordinated to a prophylactic aim. The main objective is to prevent the appearance of new cases of tuberculosis.

Some of the finer details deserve comment. The most important decision has been to aim at examining 100% of the population. In two surveys at mines carried out by Dr A. L. Cochrane, of the P R U, every one of the underground workers was persuaded to volunteer for radiography. In both these surveys it was found that there was a higher proportion of clinically significant tuberculosis in those who were the last to come forward for examination than among the earlier volunteers. This suggests that present mass radiography studies, in which little as 20% of the population may volunteer, are missing many more cases than the sponsors recognise. The decision to use full size films for miners is based on a trial of various miniature radiographic techniques, one of which was found capable of revealing early pneumoconiosis. This is of interest since large numbers of miners in this country are still being radiographed with miniature films, with inevitably misleading results. The usual technique of reading small films will be modified in the light of the work of Yerushalmy and others in America.³ Three doctors will read all the small films independently, and large films will be taken of all those identified as clinically significant tuberculosis by any of the three. The large films will be read in triplicate in the near future, and any case read as clinically significant for tuberculosis by any of them will be clinically investigated. It is probable that these triplicate readings will greatly increase the efficiency of case-finding.

This pioneer study in the epidemiology of tuberculosis will also be used to investigate the aetiology of the most

serious form of coalminers' pneumoconiosis. If the follow up shows that the attack rate of massive fibrosis among cases of simple pneumoconiosis is much decreased it may show one way in which medical supervision may combine with dust prevention to reduce the serious incidence of disabling pneumoconiosis among coalminers. The results of this part of the inquiry will of course, depend on whether massive fibrosis is of tuberculous origin, and, if so, whether it is due to endogenous or exogenous infection.

PAY OF THE PSYCHIATRIC SOCIAL WORKER

QUALIFICATIONS lose their value when they become common currency. "When everyone is somebody then no one's anybody." But when those who hold a particular qualification are few, and the openings for their services many, they naturally acquire a scarcity value which people with appointments to offer generally recognise in a practical manner. Psychiatric social workers, who are both scarce and highly trained, have lately suffered a curious affront in an advertisement (reproduced in full by Dr Sessions Hodge in his letter on p. 271) which asks for applications for the post of mental health worker, and offers higher remuneration to "unqualified persons." Even after five years the qualified psychiatric worker is to get less than the starting salary of a woman without this qualification.

Whatever may be said against the tract displayed in the wording of this advertisement, we can all be grateful to the drafter for bringing an injustice into sharp relief. Psychiatric social workers normally hold a social science diploma or degree, which means two or three years at a university, followed, after a period of practical experience, by a further year's study at a university for a mental health certificate, but they are paid on a scale of £370-530 negotiated between voluntary hospitals and medical auxiliaries before the National Health Service started. This scale should have been revised long ago, but the Whitley Council has been unaccountably slow in reaching agreement. Because psychiatric social workers are scarce Nottinghamshire has thrown the posts open to other mental health workers. These are mostly ordinary social workers—some of them holding a social science diploma—who will receive their mental health training "on the job." These workers were not tied down by a previous agreement and have acted through their association, with the result that the Whitley Council machinery has been used on their behalf. The Nottingham County Council have graded the post as that of a senior social worker and are offering the A.P.T.V. (administrative, professional, and technical) scale of the National Joint Council for employees of local authorities—i.e. £480-525. The advertisement, however, lumps together the psychiatric social workers and the social workers holding a diploma in social science, and awards them the inferior scale which applies only to the psychiatric social worker (though she holds an additional qualification). In the next sentence it refers to "unqualified persons" when it really means social workers not holding either the diploma or the mental health certificate.

The psychiatric social workers undoubtedly have been, and are being, penalised by the slowness of their negotiations. To complete a paradoxical story, the Ministry of Health, having appointed a committee to inquire into the causes for the scarcity of these workers, has not so far published its interim report submitted a year ago. Meanwhile this rare and valuable bird will probably become rarer, if not extinct. As Gilbert might have put it, "when somebody is nobody, there won't be anybody."

Prof. JEAN VERHOOGEN, of Brussels, for many years chairman of the international committee of the Société Internationale de Chirurgie, died on July 24 at the age of 86. He was an honorary fellow of the Royal College of Surgeons of Edinburgh.

President Mr B L MCFARLAND

Tuberculous Arthritis of the Hip joint

Mr H J SEDDON said that it was now generally accepted that sound arthrodesis in the optimum position should be secured after the disease had become quiescent, and that some type of grafting operation based on the work of Trumble and of Brittain was perhaps the best means of obtaining it. There was general disquiet, however, about the side effects of the long continued immobilisation in recumbency which H O Thomas and his pupils had insisted was necessary to obtain quiescence. The renal lesions were well known, but demineralisation of the skeleton was common, the thoracic cage often altered in shape, and premature fusion of the epiphyses above and below the knee could lead to gross shortening. Much of this could be avoided by applying the mobile suspension apparatus developed by E J Nangle and others, but the disadvantage of a fixed hip joint would remain. Until the advent of streptomycin the prospects of obtaining useful movement had been poor. For the badly damaged joint, Bankart's radical excision was seldom required, and Adam Grucza of Warsaw was perhaps alone in advocating a type of arthroplasty as a routine procedure. With streptomycin, which gave some hope of retaining the normal mechanism of the joint, early diagnosis and pathological proof were essential. Biopsy of an iliac gland was still a useful diagnostic procedure, but arthrotomy to obtain a specimen of synovial membrane now carried fewer risks and should not be delayed in cases of doubt.

Mr R S GARDEN spoke about the difficulties of early diagnosis. If a child's limp persisted after a week in bed complete investigation was warranted. An early sign of muscle spasm was loss of rotation movement, which could easily be detected with the child lying down by flexing both hip and knee to a right angle and using the lower leg as a pointer.

Mr DILWYN EVANS described with reserve the promising results obtained with streptomycin in the treatment of early cases in the South Wales area. It was still much too soon to arrive at any definite conclusions, but the results to date justified some degree of optimism. There had been few side effects from the standard dosage of 1 g daily for 90 days. Mr E WARDLE discussed the surgical treatment. In 27 out of 34 cases he had obtained sound arthrodesis from an iliofemoral graft placed just above the neck of the femur, and he thought this a better procedure in children than Brittain's operation. Dr J DOBSON read a fascinating paper giving an analysis of 320 cases treated by a variety of methods. A high proportion of patients discharged with fibrous ankylosis returned with sequelae needing further hospital treatment, this was rare when bony ankylosis had been secured. He regarded Brittain's operation as a good one in children (an opinion which was shared by several other speakers). The human type of bacillus had been found in every case (68) investigated from this aspect. The average period before the diagnosis was made was ten months.

In the discussion which followed, Mr NORMAN CAPENER recalled the work of Blundell Jones on the persistence of streptomycin injected into the knee joint. Appreciable concentrations remained for as long as four weeks—a finding which suggested that intra articular injections of streptomycin at intervals of one or two weeks might be a rational adjunct to the systemic therapy, especially for the early synovial type of lesion. The PRESIDENT emphasised the value of osteotomy with inward displace-

ment in the operative technique of arthrodesis, regarded this as a most important reason for the of Brittain's procedure.

Treatment of the Short Leg

Mr G E THOMAS reviewed the numerous equalisation, varying from alteration of the heel of shoe to amputation and an artificial limb. With to conservative measures he recalled that the Of extension type of boot had been demonstrated at meeting of the B.M.A. in 1899, and was still a appliance, particularly for men with shortening of 4½ inches. With tibial lengthening he had often degenerative changes in the ankle joint from the pressures developed by distraction, elongation of Achilles tendon left many soft tissues to be stretched and fresh deformities in the foot could follow, the fibular fragment carrying the lateral malleolus often pulled upwards. Various methods of equalisation in children, such as lumbar sympathectomy, epiphysodesis, stapling of epiphyses, and shortening of the short limb were fully discussed.

Mr F G ALLAN reported his experience of 101 cases of leg lengthening, 54 of the tibia and 47 of the femur. Tibial lengthening was used chiefly for infantile paralytic (30 cases), and femoral lengthening for the short leg secondary to tuberculosis of the hip (18 cases). The average increase in length obtained from the tibia was just over 2 inches, and from the femur just under 2 inches. Provided there had been minimal interference with the soft tissues during the operation for distraction of the bone, care during the stage of distraction could avoid most of the complications mentioned by various writers.

Mr A L EYRE BROOK discussed the techniques of bone shortening, either by arrest of epiphyseal growth or by shortening of the femur or tibia. The use of staples across the epiphyseal line on either side of the femoral or tibial condyles to control bone growth was still an experimental procedure, though it was giving encouraging results. For stopping epiphyseal growth altogether, he preferred a much more extensive curettage of the cartilaginous plate than was generally recommended, bony closure of the epiphyseal line should be visible in three months. In the older age groups bone shortening was simple, safe, and exact. For the femur straightforward overlap of the bone ends with transverse screws could be used, but in the subtrochanteric region a Blount plate gave good fixation.

In the discussion which followed Mr SEDDON commented that leg equalisation was a procedure best left to one surgeon in each area. Mr H OSMOND CRAMPTON asked that surgeons should temper their enthusiasm for bone shortening in men when the consequent benefit would approach five feet six inches. He also mentioned Swedish work on the production of arteriovenous aneurysm to stimulate bone growth in the lower limb.

Treatment of Acute Osteomyelitis

Prof W MERCER said that the main problems in the treatment of osteomyelitis at present were those of early diagnosis, the best use of penicillin and other antibiotics, and the type of surgery to be recommended, if any. His experience penicillin at a constant blood level of 0.1 unit per ml often sufficed up to the age of 5, from 5 till 10 years surgical treatment was often indicated but over 10 years it was always required. He suspected insensitivity to penicillin in 5% of cases, and stressed the need for the appropriate tests in all cases. The surgical technique to be employed could not be decided, his own preference was for incision, drainage,

ne, the local application of penicillin, suture in
yers, and splintage in plaster of paris

Dislocations

OSMOND CLARKE related a number of examples of
ation, torn ligament, or displacement of bone into
, any of which might not be recognised by ordinary
d or radiographic examinations. Subluxation of
cervical vertebrae was often missed on account of
to take films with the neck flexed. Complete
of the internal lateral ligament of the knee or of
ternal lateral ligament of the ankle usually required
taken with firm strain on the ligament for their
recognition. Displacement of the medial epicondyle
of humerus into the elbow joint was often overlooked
in the presence of damage to the ulnar nerve. He
red that the completely torn internal lateral ligament
of the knee should be carefully exposed and lightly
ed before fixation of the joint in plaster, on the
hand the conservative treatment of the torn
lateral ligament of the ankle rarely left any
as instability.

Condylar Fractures of the Humerus

F. W. HOLDSWORTH discussed the treatment of
condylar fractures in children. The results of all
s of operative reduction were uniformly bad, but
ated manipulations to improve the reduction were
much better. The bone ends were often thin plates
the edges of a broken dish, and impossible to hold
tly reduced. In a recent review of 45 cases with
primary displacement examined after three or more
s, he had found all the parents satisfied and little
ence of impaired function in the elbow in any case.
treatment of the fracture the arm should be supported
a simple collar and-cuff sling at 45° flexion of the
w, he was averse to any form of plaster cast.

Intertrochanteric Fractures of the Femur

Dr NORMAN ROBERTS reported the results in 50 cases
of intertrochanteric fracture of the femur treated in the
six years, the average age being 62. Of the 48 cases
ed, 35 had been treated by fixation with a tri-fin nail
plate, complete technical success was achieved in
and 8 cases were regarded as partial failures for
ious reasons. There was no operative mortality.

Roberts thought that internal fixation was a
cedure of undoubted value in selected cases.

OCCUPATIONAL HEALTH

President Dr DONALD HUNTER

Organic Phosphorus Insecticides

Dr LESLEY BODSTRUP said that the Germans developed
powerful organic phosphorus insecticides during the
19-45 war, to protect their limited food supplies. Both

U.S.A. and Great Britain have made use of these
compounds, which can be lethal to man as well as to
red spider and aphides. 'Parathion' is the most
notable because, unlike H.E.T.P. (hexa ethyl tetra-
phosphate) and T.E.P.P. (tetra ethyl pyrophosphate), it
stable and gives longer protection to the plant. These
compounds are toxic because they inhibit the enzyme
cholinesterase.

Dr F. A. DENZ explained their mode of action.
Acetylcholine is normally liberated at the parasympa-
tic nerve-endings and at the myoneural junctions
is rapidly hydrolysed in the presence of cholinesterase.
This enzyme is destroyed, acetylcholine 'persists',
producing the muscarinic effects—flooding of saliva,
inching of tears, intestinal colic, and bronchospasm.
These symptoms are relieved by atropine.

Dr BODSTRUP emphasised another danger of parathion
poisoning is insidious and mosses develops at a late stage.
H.E.T.P.P. and H.E.T.P., on the other hand, constriction
of the pupils occurs early so the victim is forced to give

up his work because he cannot see properly. Early
treatment with atropine, gr $\frac{1}{100}$ — $\frac{1}{20}$ repeated hourly
until the pupils are dilated or pulmonary oedema has
subsided, is essential. The combination between cholin-
esterase and parathion is irreversible after a few hours.
Restoration of cholinesterase can only take place by
regeneration after weeks or months. The muscular
paralyses are the danger signals and are unaffected by
atropine, but prolonged artificial respiration can save
life. In factory and field, absorption of parathion
through the skin and by inhalation could be prevented,
but reliable protection is so elaborate that parathion
users must be closely supervised.

There was force and a welcome objectivity behind this
paper, but Dr MAURICE GOLDBLATT, commenting on
its restrained tones, said there is full justification for
more violence. As time goes on, these insecticides with
their incomparable properties of destruction will be
applied in greater measure. Education of users is an
arduous task but should be pursued, since proposals to
ban sales of these insecticides are not likely to be accept-
able in view of their importance to agriculture and
horticulture.

Prof R. E. LANE suggested issuing to everyone
exposed a card describing the signs, symptoms, and
treatment of parathion poisoning. This could be
handed to the doctor, who might be ignorant of the
nature and the treatment of such a bizarre illness. A
similar procedure was adopted many years ago by the
Factory Department for industrial anthrax.

Dr ALAN DAVID summarised the principles of control
as training and education, the provision of protective
clothing, of gas proof cabs for drivers who are spraying,
and of supplies of atropine in sealed containers for those
at risk, and routine medical examinations, including
estimations of cholinesterase in blood and plasma.
Finally, Dr LESLIE NORMAN recommended that the
Ministry of Health should be asked to inform all medical
practitioners in rural areas about this toxic hazard, for
which there is an antidote.

All agreed that here is a new danger to the peaceful
inhabitants of rural England, and that the Government,
industry, and doctors should take warning from the 100
cases of poisoning recorded in the U.S.A. in 1949.

Medical Examination in Industry

The second session was more controversial. Dr A.
THELWALL JONES shattered the well-established beliefs
of industrial medical officers by suggesting that the
pre-employment and periodical medical examinations
were hardly worth while. He argued that in most
industries the labour turnover is so high that the value
of the pre-employment examination is lost. The usual
conditions leading to rejection can be observed by a
competent labour officer. The examination at regular
intervals of men working on hazardous processes rarely
detects disease, and the periodic health 'check up'
should be condemned. To advocate it is to deceive the
patient and the doctor, serious disease could develop
within a month or two after a satisfactory medical
examination. As an alternative, industry should develop
the principle of voluntary consultation for all workers
and not encourage its doctors to become preoccupied
with job analysis and statistics. Dr R. F. L. LOGAN des-
cribed Dr Thelwall Jones's remarks as a healthy
tornado. Present methods are out of date and relics of
the times when many young persons with gross disease
applied for work. Today the few who are obviously
unfit for industrial work are screened off by the school
medical service, and yet the same type of medical
examination is continued in industry.

Dr NORMAN said that it was not antisocial to advise
a worker against taking a job for which he was ill-suited.
To allow a tall man to become a bus conductor would

make him liable to an occupational kyphosis and constant irritation, he would void his duties on the upper deck and become inefficient. Rather should there be a Society for the Prevention of Cruelty to Workers to protest against such misemployment. Medical examinations are of service to the group as well as the individual. Misfits at work are a source of danger to other workers and to the public. One of the main points of advance in medicine may well be the detection of the subhealthy by periodical examinations, bringing to them early treatment before disease has developed.

The opinions of the majority, expressed by Dr LLOYD POTTER, was that Dr Thelwall Jones had not appreciated that a good clinician could be a practitioner of preventive medicine. To wait for the worker to consult the doctor might be to wait in vain. Professor LANE, supported by Dr A. J. ORENSTEIN, said that medical examinations are essential in hazardous occupations, and give confidence and comfort to those exposed. It is a pity that they are not extended to all the dangerous trades.

The moral of this controversy appeared to be new techniques in medical examination should replace the old ones, but to rely solely on the voluntary consultation would be to return to the methods of the ancient apothecary.

PREVENTIVE MEDICINE

President Prof W. M. FRAZER

Social Medicine

"Provocative, realistic, and essentially practical" describes the two day discussion on social medicine opened by Prof J. M. MACKINTOSH.

The present day tendency to overspecialisation, invading the personal relationship of doctor and patient, had, he said, led to the danger of thinking only of affected organs while remaining blind to the patient's medico-social needs. There was a risk that hospital treatment, ever more complex, might become too obscure for the family doctor, who would come to live in a world of make believe in which he was told that he was the backbone of medicine, health adviser to the family, and the front line attack on disease, but in which in reality he handed out prescriptions, signed forms, sign posted patients into hospital, and waged a long drawn out war of financial competition. One after another, mother, infant, toddler, school child, the tuberculous, the diabetic, the rheumatic, and now the aged sick straggled in long procession to hospital, and soon the family doctor might not be expected even to mend a tear of the skin. Drastic, if controversial, remedies were needed. Professor Mackintosh reiterated his proposal that medicine should be governed by charter, along the lines of the B.B.C. and Department of Scientific and Industrial Research. This would open the way to revision of the method of remuneration. Doctors must practise their art in teams, not separately as rivals, and this required the abolition of the principle of payment per patient or per service and replacement by salary scales based mainly on length and efficiency of service and on the type of area served.

Dr FREDERICK HALL urged better training of the undergraduate in a knowledge of the organised health services provided by local authorities and of the environmental and social influences which played so important a part in the physical and mental conditions which the family doctor was expected to treat. Dr J. D. KERSHAW spoke of the need for study of social factors not only in relation to disease but as an essential preliminary to the provision of an optimum environment in which man can realise his full potentialities. A new concept of social medicine might be obtained by thinking of "dis-ease" in the literal sense as a "disturbance of ease," and of the patient as a person whose mode of life and success in living were threatened. Surgeon Rear-Admiral Sir SHELDON DUDLEY, F.R.S., favoured a salaried service not depending on the number of sick treated. "We shall do

nothing in the National Health Service till we have a salaried service."

Social Medicine from the Standpoint of the M.O.H.

Dr C. FRASER BROCKINGTON spoke of a community relationship similar but distinct from the doctor-patient relationship of the family and the doctor. Areas should not be too large for the officer of health to make an intimate study of community health problems in his district—a population might not exceed say 100,000–150,000. Dr Brockington's opinion he should be given priority for the industrial health service in his area. Close cooperation needed locally between the hospital, and the general practitioner, had poignantly demonstrated in the Radcliffe survey which showed that owing to lack of an effective system of follow-up 75% of the patients failed to follow up fully from hospital care. The practice of public health required full specialist recognition. He would like the introduction of a registrar grading in public health training, and, after the present twelve months' training for the D.P.H., a year spent in the academic study of social medicine followed by a year's study of the health services abroad before entering the community health services in this country. Speaking of the work of the health visitor, he argued that the balance of training was now wrong. Two years' basic nursing was enough, whereas training in the social sciences needed to be extended at least two years.

Dr J. GREENWOOD WILSON thought there was not much wrong with the present training of the health visitor, who in Cardiff, since 1944, had become, in addition to her other duties, the key worker in a home follow-up scheme, now provided for in the after-care provisions of section 28 under the National Health Service Act. The health visitor knew her family and was in a unique position to co-operate with the family doctor in securing necessary help when patients come out of hospital. In this way the health visitor saved the doctor's time in much unnecessary detail, and by supplementing his lines of communication with the hospital service—particularly with the hospital almoner.

Dr E. HUGHES doubted whether we knew our work in administration the future of social medicine was work to best advantage. All parts of the National Health Service Act, he thought, required to be administered by a single ad hoc body. The wide scope for the part of social medicine under the National Assistance Act should not be lost sight of, nor the part the health visitor should play in an industrial health service. The health visitor was a technical officer whose training need necessarily be extended in the sphere of social work. Dr B. G. GREYTON-WATSON referred to the mounting costs and growing complexity of the curative services. He deplored the passing over of the chest clinic to the hospital service while local authority services remained what were in effect an extramural extension of the curative and rehabilitative activities of the hospital. Prevention had been forced into the background, a revival was assured. Not until it became known how to prevent the many diseases now filling our hospitals would the real purpose of social medicine be achieved.

Care of the Tuberculosis Patient in the Home

At a joint meeting with the section of diseases of the chest and tuberculosis Prof F. R. G. HEAF said that owing to the lack of sanatorium beds, 137,000 tuberculous patients were having to be treated in their homes. Patients whose homes were poor should, he thought, have priority for admission to sanatoria. Tuberculous patients must be free from financial anxiety, cooperation, and with proper opportunities for rest. Complicated cases must be treated in hospital, and collapse therapy

me should be used with care. Streptomycin not be given indiscriminately, because of the of spreading resistant organisms. He suggested general practitioners should consult the chest man before giving streptomycin to their patients. It should be examined and children who were not negative should be given B.C.C.

R. GRENVILLE MATHERS regarded the chest clinic as the chief centre for the treatment of tuberculosis. However, he said, cases suitable for active treatment selected for admission to sanatorium for collapse, and as soon as this was established they were urged to continue treatment at home. Mothers and housewives were unsuitable for domiciliary care, needed home help, and sometimes could not help them. Of the children referred to the clinic in 1949, 65% had had no known contact with a recognized case of tuberculosis; the unknown case was the mother. Dr W. D. GRAY said that of 140 adult patients requiring admission to hospital in the North Liverpool TB Hospital, 52 were able to rest in bed in a single room, 5 had shared a room with others, 35 were unable to rest, and 28 were unwilling.

In the discussion which followed Dr GRENFORDWOOD also advocated free home help for the tuberculous.

DERMATOLOGY

President Mr R. STOPFORD TAYLOR

Therapy of Venereal Diseases—its Uses and Abuses. Dr ROBERT LEES advocated the use of penicillin and thionamides in gonorrhoea but added that reliable tests to establish diagnosis and cure are essential. He felt streptomycin if coincident syphilis is suspected. A dosage with penicillin may conceal syphilis. Empirical treatment and neglect of ancillary treatment are common abuses and he considers that the use of penicillin month to prevent venereal disease is an abuse. In late syphilis penicillin alone may be curative, he said, but the amount of drug and the duration of administration required are still unknown. It is common practice to combine the use of penicillin, bismuth, and arsenic. He suggested a treatment schedule in two phases: (a) a very intensive attack lasting 2-3 weeks, with penicillin, bismuth, and arsenic, and (b) a prolonged phase of 6 months, in which arsenic and bismuth are given but not intensively. The place of penicillin in the treatment of late syphilis is still unsettled but it is very valuable in syphilis of the central nervous system. It may be useful in cardiovascular lesions, provided it is used cautiously and the patient is properly prepared with slow acting drugs. Congenital syphilis can be prevented completely by antenatal treatment, which should consist of penicillin and bismuth, but not arsenic. Special technique is needed for lesions such as interstitial keratitis. In the treatment of syphilis the abuses are overdosage especially in congenital syphilis and in cases with "fixed" positive serum reactions. Under treatment of early syphilis (a few doses of penicillin being given, often without established diagnosis) (3) local applications of penicillin, and (4) treatment of healthy persons wrongly suspected of syphilis.

Dr SYDNEY M. LAIRD said that chemotherapy represents a fundamental advance over the symptomatic treatments of earlier centuries. The principles of usage, which are essentially the same, irrespective of the chemotherapeutic drug given, should be clearly understood and failure to observe these principles constitutes an abuse of chemotherapy. Three important factors are virulence of the organism, the natural defensive powers of the patient, and the efficacy of the drug. The last depends on the sensitivity of the pathogenic organism and the tissue level of the drug which can be

established at the site of infection. The combined use of chemotherapeutic agents may sometimes be advantageous. Accurate bacteriological diagnosis before treatment, and adequate post treatment observation, are essential. One injection of penicillin is usually adequate for an uncomplicated gonorrhoeal infection. In complicated cases longer chemotherapy and local treatment may be required. Penicillin has established its place in the treatment of all stages of syphilis and with few exceptions should replace the arsenic compounds. Bismuth compounds should be combined with it in all stages. In late syphilis bismuth should precede penicillin, to reduce the risk of Herxheimer reaction and therapeutic paradox.

Dr D. J. CAMPBELL said that treatment with early preparations of penicillin, and less than 150,000 units, had given a high and immediate cure rate for gonorrhoea in males. He preferred the oily preparations, but modern syringes make them somewhat unmanageable. He thought this relatively small dosage desirable because it is less likely than a larger dose to mask incubating syphilis. Alternatively dosage should be increased so much as to make certain of eradicating any possible syphilis. He regards penicillin as the drug of choice in early syphilis and agreed with Dr LEES on the treatment of late syphilis. Dr D. I. WILLIAMS discussed the place of dimercaprol (BAL) in the treatment of metallic intoxications and thought it should be employed in all but the mildest cases of arsenical dermatitis. Colonel CLIFFORD MORCAN (U.S. Army) spoke of the help the Central Guidance Bureau has given in reducing the incidence of venereal disease in the Forces. Dr DONALD HUGGINS (Trinidad) discussed the necessity for an effective short course for the treatment of early syphilis in the West Indies. Dr A. M. STUART stressed the need to treat the wife, without necessarily waiting for positive laboratory findings, when the husband is known to be infected with gonorrhoea.

Dr J. P. G. ROGERSON spoke of the importance of the small communities—e.g., 10,000 persons—and the difficulty of attendance at clinics more often than once a week because of distance and transport.

A discussion on *Parasitology in Relation to Dermatology*, held jointly with the section of tropical medicine, was reported on July 29 (p. 185).

ANÆSTHETICS

President Dr KATHERINE LLOYD-WILLIAMS

Applied Pharmacology in Anaesthesia for Abdominal Operations.

Dr STUART C. CULLEN (Iowa City, U.S.A.) described a method of anaesthesia with several drugs in which each component contributed special virtues. Nitrous oxide was the essential anaesthetic, the rest being used either to allow sufficient oxygen to be administered with the nitrous oxide or to provide muscular relaxation. Reflex irritability and metabolic activity were first depressed with such drugs as the barbiturates, morphine or its substitutes, scopolamine, or bromethol ('Avertin'). In premedication he favoured morphine and scopolamine rather than pethidine, which produced little psychic effect. Induction was with thiopentone and anaesthesia was maintained with nitrous oxide administered by the semi closed carbon dioxide absorption method. Pethidine was injected intravenously in repeated doses, and curare was added to produce relaxation. The patient was intubated. Care was necessary during his recovery if large doses of depressants had been given.

Dr WILLIAM MUSHIN had found that this technique gave good results in terms of rapid recovery, freedom from sickness, residual analgesia, flexibility, good operating conditions, and absence of explosion risk.

make him liable to an occupational kyphosis and constant irritation, he would avoid his duties on the upper deck and become inefficient. Rather should there be a Society for the Prevention of Cruelty to Workers to protest against such misemployment. Medical examinations are of service to the group as well as the individual. Misfits at work are a source of danger to other workers and to the public. One of the main points of advance in medicine may well be the detection of the subhealthy by periodical examinations, bringing to them early treatment before disease has developed.

The opinions of the majority, expressed by Dr LLOYD PORTER, was that Dr Thelwall Jones had not appreciated that a good clinician could be a practitioner of preventive medicine. To wait for the worker to consult the doctor might be to wait in vain. Professor LANE, supported by Dr A. J. ORENSTEIN, said that medical examinations are essential in hazardous occupations, and give confidence and comfort to those exposed. It is a pity that they are not extended to all the dangerous trades.

The moral of this controversy appeared to be new techniques in medical examination should replace the old ones, but to rely solely on the voluntary consultation would be to return to the methods of the ancient apothecary.

PREVENTIVE MEDICINE

President Prof W. M. FRAZER

Social Medicine

"Provocative, realistic, and essentially practical" describes the two-day discussion on social medicine opened by Prof J. M. MACKINTOSH.

The present-day tendency to overspecialisation, invading the personal relationship of doctor and patient, had, he said, led to the danger of thinking only of affected organs while remaining blind to the patient's medico-social needs. There was a risk that hospital treatment, ever more complex, might become too obscure for the family doctor, who would come to live in a world of make-believe in which he was told that he was the backbone of medicine, health adviser to the family, and the front-line attack on disease, but in which in reality he handed out prescriptions, signed forms, signed patients into hospital, and waged a long drawn-out war of financial competition. One after another, mother, infant, toddler, school child, the tuberculous, the diabetic, the rheumatic, and now the aged sick straggled in long procession to hospital, and soon the family doctor might not be expected even to mend a tear of the skin. Drastic, if controversial, remedies were needed. Professor Mackintosh reiterated his proposal that medicine should be governed by charter, along the lines of the B.B.C. and Department of Scientific and Industrial Research. This would open the way to revision of the method of remuneration. Doctors must practise their art in teams, not separately as rivals, and thus required the abolition of the principle of payment per patient or per service and replacement by salary scales based mainly on length and efficiency of service and on the type of area served.

Dr FREDERICK HALL urged better training of the undergraduate in a knowledge of the organised health services provided by local authorities and of the environmental and social influences which played so important a part in the physical and mental conditions which the family doctor was expected to treat. Dr J. D. KERSHAW spoke of the need for study of social factors not only in relation to disease but as an essential preliminary to the provision of an optimum environment in which man can realise his full potentialities. A new concept of social medicine might be obtained by thinking of "dis-ease" in the literal sense as a "disturbance of ease," and of the patient as a person whose mode of life and success in living were threatened. Surgeon Rear-Admiral Sir SHELDON DUDLEY, F.R.S., favoured a salaried service not depending on the number of sick treated. "We shall do

nothing in the National Health Service till we have a salaried service."

Social Medicine from the Standpoint of the M.O.B.

Dr C. FRASER BROCKINGTON spoke of a community relationship similar but distinct to the doctor-patient relationship of the family and doctor. Areas should not be too large for the officer of health to make an intimate study of community health problems in his district—a population might not exceed say 100,000–150,000. Dr Brockington's opinion he should be given responsibility for the industrial health service in his area, close cooperation needed locally between the hospital, and the general practitioner, had poignantly demonstrated in the Radcliffe survey which showed that owing to lack of an efficient system of follow-up 75% of the patients failed to follow up from hospital care. The practice of public health required full specialist recognition. He would like to see the introduction of a registrar grading in public health training, and, after the present twelve months' training for the D.P.H., a year spent in the academic study of social medicine followed by a year's study of the health services abroad before entering the community health services in this country. Speaking of the work of the health visitor, he argued that the balance of training was now wrong. Two years' basic nursing was enough, whereas training in the social sciences needed to be extended at least two years.

Dr J. GREENWOOD WILSON thought there was much wrong with the present training of the health visitor, who in Cardiff, since 1944, had become in addition to her other duties, the key worker in a home follow-up scheme, now provided for in the care of aftercare provisions of section 28 under the National Health Service Act. The health visitor knew her family and was in a unique position to cooperate with the family doctor in securing necessary help when patients came out of hospital. In this way the health visitor saved the doctor's time in much unnecessary discussion and by supplementing his lines of communication with the hospital service—particularly with the hospital almoner.

Dr E. HUGHES doubted whether we know our health administration the future of social medicine work to best advantage. All parts of the National Health Service Act, he thought, required to be administered by a single ad hoc body. The wide scope for the practice of social medicine under the National Assistance Act should not be lost sight of, nor the part the health visitor should play in an industrial health service. The health visitor was a technical officer whose training need not necessarily be extended in the sphere of social work. Dr B. G. GRETTON-WATSON referred to the mounting costs and growing complexity of the curative services. He deplored the passing over of the chest clinic to the hospital service while local authority services remained what were in effect an extramural extension of curative and rehabilitative activities of the hospital. Prevention had been forced into the background and a revival was assured. Not until it became known to prevent the many diseases now filling our hospitals would the real purpose of social medicine be achieved.

Care of the Tuberculosis Patient in the Home

At a joint meeting with the section of diseases of the chest and tuberculosis Prof F. R. G. HEAF said that owing to the lack of sanatorium beds, 137,000 tuberculous patients were having to be treated in their homes. Patients whose homes were poor should, he thought, have priority for admission to sanatoria. Domestic patients must be free from financial anxiety, cooperation, and with proper opportunities for rest. Complicated cases must be treated in hospital, and collapse therapy

FRAY referred to the noradrenaline secretion by tumours, and thought that the adrenaline secreted lured by the anaesthetic. He suggested the treatment might be to inject more adrenaline. Dr A C BSTER described 8 cases of these tumours, the pressure always fell, he said, when the clamp was on, but it was readily controlled with an injection of adrenaline. Dr F L DYSON advised a trial of drugs 'Dibenzamine' and 'M & B 933F' in these cases.

NEUROLOGY

President Sir HUGH CURRAS

President of Parkinsonism

HUGH GARLAND said that whatever the lying cause, parkinsonism always appeared to be from destruction of ganglion cells in the extrapyramidal system. The commonest form was paralysis agitans, underlying which there was probably an important genetic factor, the second commonest cause being encephalitis lethargica. All other causes were rare. Parkinsonism might make a dramatic appearance following sudden emotional shock. Usually the disorder was progressive, but about 30% of the post-encephalitic cases appeared to be stationary. In a survey of about half a million people he found the prevalence of parkinsonism to be not less than 1 in 1700, it would therefore appear to be at least 27,000 sufferers in Great Britain. Drugs of the solanaceous group had been used for 80 years, but in massive dosage only since 1930. Many new drugs, mostly under proprietary names, had been used in the past four years. All drugs had to be taken continuously, and usually in maximal dosage. The newer drugs might act more quickly than the older, but there was not much evidence that they were really more effective. It was very difficult to assess the value of drugs because of the very important psychological factors in any form of treatment. Oculogyric crises did not respond to drugs but might improve after anticonvulsive therapy. All forms of surgical treatment so far suggested were themselves destructive, and it so far suggested were themselves destructive, and relief of one disability might be followed by a new disability which was worse.

Dr GEORGE SMYTH said the outlook was better in the post-encephalitic case. He underlined the pre-eminence of psychological management and of physiotherapy. He agreed that there was not much evidence that the new drugs were more effective than the old, but he did not, however, feel that the future of drug treatment was necessarily hopeless.

Dr DENIS LEIGH spoke of the difficulty in assessing the use of drugs, because of the psychological factors. He drew a comparison with ulcerative colitis and rheumatoid arthritis. The best results at present were being claimed for the French preparation, 'Lysivane', which had used various drugs, employing electromyographic and other controls. Even though the measurable results were usually poor, the subjective results were frequently good. He doubted whether parkinsonism occurred only in those of a certain personality, but he emphasised the important effect of the disease on the personality, the patient finding himself isolated in a constricting world, with a sudden change in which assumed gigantic proportions. He mentioned the fluctuating response to various drugs, and he, too, doubted whether the new drugs were better than the old. Though the differences were slight, he put the drugs in the following order of efficacy: 'atropine,' 'Parpanit,' 'Benadryl,' stramonium, 'ephedrine,' and hyoscine.

Dr GEOFFREY JEFFERSON, F.R.S., said that no operation cured this disease, and a lot of the press publicity leading to surgery had been irresponsible. Surgical procedures were not difficult, and in any event British neurosurgeons were the most competent in the world. He said the desiderata for surgery should be (1) uni-

lateral involvement, not progressive or only very slowly progressive, (2) tremor the chief feature, the tremor being incapacitating, and (3) the patient's age not more than 50 or at the most 55 years. Such criteria would exclude 95% of all parkinsonians. Section of the cervical cord was the simplest procedure. Perhaps the best operation was division of the prepyramidal fibres in the anterior limb of the internal capsule.

Sir HENRY COHEN said that some postencephalitic cases derived benefit from the solanaceous drugs for many years. They became liable to chronic glaucoma, and the use of eserine was essential. He referred to our lack of knowledge of the underlying mechanisms of tremor. He thought that progression of postencephalitic parkinsonism might be due to chronic and relapsing encephalitis. He found it difficult to differentiate the aetiological factors.

At another meeting Dr M J MCARDLE opened a discussion on pain in the upper limb.

Public Health

Q FEVER IN NORTH WALES

J FORBES

M D Lond, M R C P

PHYSICIAN TO THE WREXHAM HOSPITALS

THE following case of Q fever is reported because the disease has not so far been described in this part of the United Kingdom, though there have been small outbreaks and sporadic cases in southern England (Stoker 1949, MacCallum et al 1949). The rapid response to 'Aureomycin' is in consonance with previous experience (Lennette et al 1948, Haus and Simrock 1949).

CASE RECORD

A man, aged 31, engaged in exploratory boring for opencast coal sites was admitted to the Maelor General Hospital, Wrexham, on March 14 1950. For the previous month he had been working on farmland in Flintshire. On March 10 he developed a cough, pain in the chest and severe headache. His family doctor treated him with sulphonamides and penicillin but as his condition worsened sent him into hospital.

On admission his temperature was 101.5°F. Physical examination revealed consolidation in the mid zone of the right lung and a pleural rub. Radiography showed extensive pneumonic consolidation of the right upper and middle lobes. The sputum, which was small in amount, contained staphylococci, non-haemolytic streptococci, and *Moraxella albicans*, but no pneumococci or tubercle bacilli.

Treatment with 'Sulphatrad' and penicillin was continued for three days without effect; the patient remained very ill, with a sustained temperature of 100°-102°F, occasional delirium, and constant complaint of severe headache. The absence of pneumococci from the sputum, and failure to respond to sulphonamides and penicillin suggested that the condition was virus pneumonia, or possibly Q fever. Accordingly, on March 18 treatment with aureomycin (600 mg six hourly by mouth) was begun and a sample of blood was taken for complement-fixation tests against *Rickettsia burneti* and the viruses of influenza and psittacosis.

The response to aureomycin was immediate and dramatic, great clinical improvement being apparent within 24 hours and the temperature falling to normal in 48 hours. Aureomycin was continued for seven days, the total dosage being 14.25 g. Serial X rays showed progressive clearing of the lung lesion, which had almost disappeared by March 27. Convalescence was uneventful and the patient was discharged to his home on the 31st. On April 4 the patient reported himself completely well, and an X ray film of his chest showed normal lungs.

The complement-fixation titres for Q fever were: March 17 (7th day from onset) 1/8, April 13 (34th day), 1/256, and May 30 (81st day) 1/512. The rising titres clearly indicate an infection with *R. burneti*. Complement-fixation tests for psittacosis and influenza A and B and agglutination tests for streptococcus and were negative. Cold agglutinins were absent on March 17 and again on April 1.

It has not so far been possible to trace the source of infection. The patient's fellow workmen, and the farmer

Dr T C GRAY mentioned that ether in small doses was also an effective analgesic, and Dr R F WOOLMER doubted whether there was any advantage in using more than 20% oxygen

Resuscitation of the Newborn

Dr G S W ORGANE described the breathing movements which start long before birth. During labour, he said, most of the liquor was squeezed out of the respiratory tract, and failure to breathe at birth was due to depression of the respiratory centre from such causes as anoxia or anaesthesia. The baby should be placed head downwards, and must be well wrapped up. His pharynx was cleared, and his back rubbed to stimulate breathing. Oxygen was administered and a tracheal tube was kept ready. In white asphyxia Dr Organe never used transfusion or circulatory stimulants.

Dr R J MINNITT quoted figures based on 2500 labours at the Liverpool Maternity Hospital during 1949. Where the mother had received gas and air analgesia alone no resuscitation of the babies had been necessary, but when a number of analgesic drugs had been used the proportion of resuscitations was high. During caesarean section the quicker the baby was delivered after the anaesthetic had been started the less was the likelihood that resuscitation would be needed. Lobeline and oxygen were the commonest methods used.

Dr W N LEAK, however, strongly advocated stimulants, especially a mixture of leptazol and ephedrine. Dr E H WINTERBOTTOM advocated squeezing of the tendo achillis, and Dr J DUNDEE used carbon dioxide. Dr GRACE EVANS had used trichlorethylene with little ill effect, but Dr J R GREGORY (Kenya) had found that his infant mortality had risen with the use of trichlorethylene; he strongly advised the use of chloroform.

Anaesthesia in the Newborn

Dr T N P WILTON discussed techniques used for thoracotomy in newborn infants, most of them being cases of oesophageal atresia. They were puny children, often premature, pulmonary infection or atelectasis were often already present. An intravenous infusion of blood or dilute saline was continued during and after operation. A small dose of atropine was given, and anaesthesia was induced with ethyl chloride and open oxygen and ether, the cords were sprayed with amethocaine and the larynx intubated. Oxygen and ether continued the anaesthetic, with the addition of vinyl ether if extra relaxation was needed. The respiration was controlled, for the child was easily made apnoeic. Suction was used to keep the respiratory tract clear. Patients were placed in the lateral position on the table and were watched throughout the operation for signs of collapse of the contralateral lung. The chest was drained with an underwater seal. At the end of the operation the trachea was cleared by suction, through a bronchoscope if necessary. Dr Wilton described an endotracheal connector with valve fixed on it, which reduces the dead space of the apparatus.

Dr G JACKSON REES noted that in the newborn infant, as compared with the adult, thoracic respiration was less important, since the ribs were disposed horizontally and the lung was relatively inefficient, since the area available for respiratory exchange was small, but to compensate for these deficiencies, the infant had a rapid respiratory rate. Since the trachea was relatively narrower than in the adult, resistance to breathing was increased in greater proportion if respiration became rapid. Deep levels of anaesthesia were unnecessary and so was curare, because muscle tone was virtually non-existent. He held that cyclopropane was contra-indicated in these patients, the best anaesthetic being ether—provided that the respiratory effect was reduced by controlled respiration. The child was given atropine

and brought to the theatre in a gamgee jacket; intravenous drip running into the leg. Those who were cyanosed were in an oxygen tent and was induced with nitrous oxide and oxygen and given under a Schimmelbusch mask. After the tube was connected to an Ayre's T piece, controlled respiration was used throughout the operation. At intervals the ether vapour was turned off and movement returned to the limbs. This ensured anaesthesia and recovery after operation.

Dr GRAY had used curare safely in these cases in very small doses. Mr DENIS BROWNE held that shock in these cases was due to deep anaesthesia; one must learn to operate with the child under anaesthesia, even perhaps moving. Dr MUSHIN argued against the risks of overdosing with atropine, and increasing dead space or resistance to breathing, unsuitable apparatus, and also of the possibility of cocaine poisoning through the liberal use of it.

Some Therapeutic Applications of Nerve Blocks

Dr G C STEEL reviewed the now well-known indications for nerve blocks, and mentioned the venous injection of procaine. He described one in which such an injection of 5% procaine led to about the dramatic recovery of an apparently moribund patient who had received 12 ml of 1 in 1000 adrenaline. He also recorded a case of anuria after a misplaced blood transfusion, a 'Nylon' catheter was passed intrathecally, and a continuous 'Nupercaine' block maintained for twenty-four hours. The patient improved but died sixteen days later. Dr J B HARGREAVE mentioned the risk of pulmonary embolus, and Dr MUSHIN stressed the value of nerve blocks in relieving the pain due to inoperable carcinoma.

Analgesics in Anaesthesia

Dr LESLIE RENDELL BAKER said that if nitrous oxide was to be used with adequate oxygen some curare was necessary. The latest one to be used for this purpose was pethidine, being an analgesic it was more appropriate than a barbiturate like thiopentone, which was primarily a hypnotic. If relaxation was required, he added 'Flaxedil', and the longer the operation the more striking seemed the benefits of the technique. Respiration was easily controlled in thoracic cases; cardiac or bronchial reflexes were absent, the patient awoke rapidly, and postoperative shock and sickness were notably absent. Nor was there any explosion hazard. During the anaesthesia he injected pethidine in small repeated doses together with flaxedil whenever required. No dose of pethidine exceeded 25-50 mg. Some degree of analgesia persisted for several hours after the operation.

Dr WINTERBOTTOM agreed with the choice of pethidine. He knew of three patients anaesthetised with nitrous oxide and thiopentone who had awakened and felt pain during the operation; they had been curarised and therefore could not react. Dr JOHN BULLOCK said Dr G R HOPPER used trichlorethylene as a supplement to nitrous oxide.

Sudden Death during Operation due to Undetected Paraganglioma

Dr S B DARBISHIRE reported the case of a woman of 35, who was to have a thoracoplasty for a small apical cavity. Induction was with thiopentone and tubocurarine, but no tracheal tube was used. As the 4th and 3rd ribs were being removed she became cyanosed, and thus persisted in spite of adequate ventilation with oxygen. Her heart was beating forcibly but fibrillating, 10 ml of 1% procaine was injected intravenously. She was intubated but died in spite of it. At necropsy a small tumour about 1 1/2 in. in diameter was found at the bifurcation of the aorta. Section showed it to consist of adrenal medullary tissue.

in a few days, or into the lumen of the gut, in due course it would be passed per vias naturales. The patient insists on a bit of surgery, when he recovered from the perforation, I should be obliged to oblige him with a gastroenterostomy, gastrectomy, or anything else he fancies between 9 A.M. and 5 P.M. on Mondays to Fridays.

... of professional ethics and etiquette such as M.A. recently circulated are all very well for the it among us who might be tempted to sign articles in lay press or appear undisguised in television. But a humble Peripatetic needs is practical advice, little problems arising from his non professional life with the public. What, for instance should I do when I was travelling on a Green Lane coach with a stout lady with a small boy whose persistent nasal cough even a psychiatrist could diagnose as "tussis"? The stout lady was already cross, shaking on roughly after each paroxysm, and exhorting me to "Give over, 'erbert!", and I was still weighing in my mind the community against her wrath if I told her the coach stopped and they got off. I have once or twice intervened when I saw mothers lunging their infants along in a pram with the sun shining straight into their eyes but in such cases it is to lead up to one's advice with a few remarks of the "hat-a-beautiful baby" type. Usually I don't interfere being mindful of the story of the clergyman who went across a third-class railway compartment and to a burly navvy, "Don't you know, my man, that a lot of cancers of the tongue are caused by smoking at pipe like yours?" to which the navvy retorted, "Don't you know that a lot of thick ears and blood vessels are caused by people not minding their own business?"

The painter's lot is not a happy one. In the kitchen I have spent four days studying the changing fashions in wallpaper since 1892 when this house went up. Inch by inch I removed four layers of revolting varnish, and under it all I found, pencilled on the bare plaster, rude messages and queer little sums of arithmetic some long-dead predecessor in my trade. The unkind tales from the past did not delay me, but I lost quite a little time in checking and correcting the sums. Yesterday I dabbed on some bright ocean-green paint. Only then did I realise that it looked like a yellow that had faded green or vice versa, so today I must cover the meagre territory in brighter vermilion. To crown all, I now see at the plaster, tired with age, needs the support of paper to stop it crumbling to nothing, but I haven't the length

With a common purpose we stood side by side. He is above average stature and wears a top hat of ancient vintage, a long white beard, a cravat, a long close fitting black overcoat, and leggings—altogether he looked like a coachman strayed from the Victorian era. Scarcely did I noted these details than he addressed himself to me. "Troublesome little things, aren't they?" But I shouldn't like to be without them, should we?" I agreed, to the latter question at least, and he continued, as though to justify the former. "My father used to draw off his water with a tube for the last eleven years of his life." I expressed wonder which deepened as he went on. "Amazing how he did it, seeing as he had only one arm." Then, our several tasks completed, he parted, he still wearing the topper in which may once who knows—have been coiled the tube.

This firm was quite cheered by its careful study of the findings Report. "At any rate," we said to each other, we put it down "there are worse doctors in the country than we are." Remembering that we had two examinations in couches and a number of instruments which we used quite often, we felt almost smug. Unwisely we then turned to the Cohen Report which has plunged us into the depths of gloom. It seems a long step from what we are to what we might be and an even longer step to what we ought to be—i.e., to what, according to Charles Singer, Hippocrates was. We are now turning again to the findings—he makes better holiday reading.

Letters to the Editor

SIGNIFICANCE OF THE DISCOVERY OF THE EFFECTS OF CORTISONE

SIR,—Professor Pickering, in his lecture on the general adaptation syndrome, did a public service by his strictures on the psychosomatic theory of disease. Theoretically speaking, the possible existence of psychosomatic diseases cannot be excluded but among the large variety of morbid conditions met with in general practice, one is impelled to ask oneself "where are these diseases?"

Diseases displaying psychological symptoms may be classified as follows

- 1 Psychological disease unaccompanied by physical disease
- 2 Psychological disease accompanied by physical disease
 - (a) Accidental association of physical and psychological disease
 - (b) Primary psychological disease causing bodily illness
 - (c) Bodily illness causing psychological symptoms

Most of the psychological symptoms one meets in one's everyday work appear to belong to this last group, in that in these cases the brain is behaving merely as one of the organs of the body and is functioning abnormally as the result of a bodily disease. Every day, for example one meets children suffering from upper respiratory disease. Their tonsils are enlarged. They breathe through the mouth. They may have otitis, bronchitis, muscular twitchings, or rheumatic symptoms, and at the same time they have psychological symptoms. They may be grizzling and complaining and suffering from loss of appetite. They are often mentally overactive and may suffer from nocturnal delirium and nightmares. Treatment of the upper respiratory disease—often by removal of tonsils and adenoids—leads not only, in the usual case, to recovery from the physical symptoms, but also to recovery from the psychological symptoms. A similar picture is repeated with other diseases, including the many neglected and undescribed illnesses and syndromes which occur in general practice and which do not often penetrate to the specialist level.

The confusion caused by the psychosomatic theory of disease leads to the common use of phrases such as "There is a strong psychological element in this case" or "The disease is probably functional in origin"—phrases which are not diagnoses but placebos, which can be read to mean whatever one wishes them to mean. From the practical point of view the psychosomatic theory of disease has (whatever its merits) led to the tendency to ignore proper history-taking and careful study and analysis of actual symptoms and physical signs, in favour of the glib diagnosis and the rapid prescription of a cerebral stimulant or depressant.

Not infrequently the diagnosis of psychogenic disease is based on an insufficient distrust of negative laboratory findings. The 'X ray is negative', therefore there is no osseous or articular disease! The urine is sterile therefore there is no infection of the renal or vesical tissue! The throat swab is negative therefore there is no tonsillar infection! (cf Rantz,¹ who showed in a series of cases that hæmolytic streptococci were found in 16.4% of pre tonsillectomy throat swabs, against 32.7% positive when the tonsillar tissue was cultured.)

The fault may, of course, lie in the very different incidence of diseases at the general practitioner and specialist levels, because of the highly selected type of case which the specialist studies. The rare avis of the one may be the commonplace of the other.

Oulton Broad, Suffolk.

N B EASTWOOD

and his family who work the land on which the patient was employed before his illness have all been tested serologically with negative results. The patient's wife gave a titre of 1/16 on two occasions, but this is of doubtful importance since she had had no illness of any kind in the previous year. She and her husband live in a semi-urban area with a pasteurised milk-supply, where the opportunities for acquiring Q fever seem small. It seems more probable that the patient got his infection during his work on the farm, where he would be to some extent in contact with livestock. Investigations are still proceeding, with the help of Dr J. T. Quinnan, pathologist to the Wrexham Hospitals, and Dr A. J. Kingsley Smith of the Public Health Laboratory, Conway.

The serological tests were done at the Virus Reference Laboratory, Colindale, and I am indebted to Dr F. O. MacCallum and Dr B. P. Marmion of that laboratory for their interest and helpful suggestions in trying to trace the source of the disease.

Poliomyelitis

Notifications in the week ended July 29 were: paralytic 197 (190), non-paralytic 108 (71), total 305 (261) (Previous week in parentheses).

The village of Digby, Lincs, with a population of 400, has had 15 definite and 4 suspected cases since July 10. The 130 inhabitants of a new housing estate have had 11 of the confirmed cases, with 2 deaths, but since Aug. 5 there have been no new cases on the estate, though there have been 2 or 3 suspected cases elsewhere in the Digby area. The finding of a small defect in the drainage system suggested that the estate's water-supply might be contaminated, but further investigations seem to have eliminated this possibility, and the evidence now points to the disease having spread by ordinary contact infection from the first case.

In England Now

A Running Commentary by Peripatetic Corn

Confound your geriatrics. If we live longer
More work must we do,
To pay for our upkeep and deem it a privilege
If all this much vaunted longevity
Means we can never retire,
Can't loaf with a book for the last bit,
Or snooze by the fire,
Then keep your geriatrics, brother. I'm off
for brevity.

* * *

I did a couple of appendices and a strangulated hernia between dinner and midnight. I was lying in bed with my final cigarette when the porter came and told me there was a "perf" in admissions. I was just dozing off to sleep about two hours later when he came to me of the second one. He announced the third I was consuming tea and toast with night-sister that it was not worth trying to sleep, so I burnt some cigarettes and lay down on my bed to console myself with the thought that I should be late for breakfast. I also pondered about "perfs."

Here, I pondered, is a bloke leading a fairly normal life when suddenly his peritoneum is flooded with suspension of inadequately masticated fish and chips, beer, diluted with a little gastric juice and a scoop of mucus. He feels the most ghastly pain and ends up more than somewhat from shock. Sooner or later the ham-handed louts come and throw him into a spring ambulance which proceeds directly across country and deposits him in admissions. Though he is now in hospital his tribulations are by no means over. For a nurse starts asking him if he is married, what his religion is, whether he is on the telephone, and then other silly questions. Then doctors come in and ask him with a lot more nonsense, mess him about, and finally give him what he has been wanting all along—a shot of something to dull the pain. In the end, the devious routes and with many delays, he gets what he came to the hospital for—the operation.

This, no doubt, is how it all looks from the patient's point of view. But what I kept asking myself as I dozed on my bed was: Is the operation really necessary? This chap has an irritant fluid in his peritoneal cavity which is being diluted rapidly by exudate and all the other things that the pathologists talk about. Then, just on the off-chance that the perforation has sealed itself off, this wretched fellow, shocked almost to death, is laid on the table, and, while a sleepy housemaid, disguised as an anaesthetist, pours poison in at his end, I hack a hole through his abdominal wall. On the inside, not content with disturbing the barriers that have been built up to contain the spreading fluid, I sprinkle talcum around, I must tear the omentum away from the hole in the process of blocking it, put a couple of insecure sutures through the omentum, tissue, and, to add insult to injury, clap the omentum back where I found it. Finally I patch up his abdominal wall after a fashion and leave him in bed to suffer shock, ileus, and an early bronchopneumonia as he may.

It's all wrong. When the houseman has done a "perf" he should not send for me at all. He should get the resident radiologist out of bed. Having got the patient morphine and emptied his stomach with Ryle's tube, the X-ray man should inject a little barium down the tube and screen the patient to see the leak. This, having been found, the patient should then be given a gelatin capsule to swallow in which the pharmacists have cunningly concealed a tiny gadget resembling a bath-plug, but with the plug shaped more like a cork. When the gelatin has dissolved the radiologist, with a few deft strokes, guides the plug into the hole and thus stops most of the leak. The chain of the bath plug would be so contrived that it would slough off in 5-10 minutes, leaving the plug in place. In an hour or two the omentum would have occluded the perforation completely and then the plug would be at liberty to slip either into the peritoneal cavity where its nature would cause it to disintegrate.

	1 Undecylonic acid	2 Controls	3 Calciferol
Patients	30	19	19
Dose	8 g	—	100 000 units
Duration of treatment	8 weeks	9 weeks	6 weeks
	None	1 (5%)	6 (32%)
Improved	5 (17%)	5 (26%)	4 (21%)
Improvement	3 (10%)	7 (37%)	6 (32%)
Not improved	19 (63%)	4 (21%)	2 (10.5%)
Not treated	3 (10%)	2 (10.5%)	1 (5%)

will be seen that in this series there was no evidence of benefit from undecylonic acid, and these findings are in accord with other published reports.⁴ It seems that in assessing the response to treatment of conditions such as psoriasis, the results obtained in a small uncontrolled group of cases are useless. It also seems that it would be wiser to publish early reports, that of Perlman, in a journal of investigation and research than in one with a wide and general circulation.

STEPHEN GOLD

London, W 1

EOSINOPHIL-COUNTS

SIR,—In your leading article of June 3, you drew attention to the possible errors in estimating adrenocortical function by means of eosinophil counts, and underlined the importance of a reliable counting technique.

This seems an appropriate moment to recall a "wet" technique described by me some years ago.⁵ The method is based on a dibasic chrome, using two vitalising basic dyes—an oxazine and an azine aniline dye obtained from Messrs Bayer, Hoechst Frankfurt. The solution fluid is

New blue R 0.1 g
Rhodamine violet* 0.05 g
Aqua dest ad 100 ml

* A safranin derivative

This technique is the same as for an ordinary leucocyte count, the only difference being that this solution is used for dilution of the blood. The eosinophil granules are stained dark bluish black and cannot easily be overlooked, the cell nuclei are stained light violet. Lymphocytes, monocytes, and neutrophils and basophil granulocytes can be differentiated. The method can also be used for Arneith counts.

M G GOOD

ENURESIS IN ADULTS AND ABNORMALITY OF SLEEP

SIR,—I can support much of what Dr Strom Olsen says in his article of July 22, about the association of nocturnal enuresis with hypersomnia.

I have 28 enuretics at the Portman Clinic being treated with 'Dexedrine'. These cases, of which 26 are children between the ages of six and sixteen, are or have been attending the clinic for behaviour disorders or delinquencies, the enuresis being a secondary symptom, indeed often one of many symptoms of a psychoneurotic order. In this latter respect they do not conform with the description of a non-neurotic type given by Ström Olsen.

In my series dexedrine in doses of 5–15 mg has been very effective in stopping bed wetting in 19 cases, very helpful in another 4. In 6 cases an inert placebo was given as a control, with very temporary improvement or no good effect at all. In 2 cases

where the patients were disturbed by sleeplessness the treatment was terminated.

My impression is that the dexedrine effect is likely to be accounted for by postulating both a central influence on the hypothalamic centres associated with sleep and micturition, and also a cerebral effect in its well-recognised ability to produce a sense of well-being, security, and confidence so much lacking in these children.

CHARLES LEWSEN

INOCULATION CERTIFICATES REQUIRED ABROAD

SIR,—From a considerable experience of travelling to countries round the Middle East during the last five years, I can strongly support Sir Philip Manson Bahr's plea for a system by which authoritative information can be obtained as to the requirements of various governments regarding certificates of vaccination and inoculation. Regulations are frequently changed owing to epidemics arising in various countries.

The confusion is exemplified by a statement in Sir Philip's letter. He emphasises the necessity for possessing certificates of smallpox and yellow fever inoculation by all travellers to Egypt, whether visitors or passengers in transit. While this is correct for those who approach Egypt from the south or east, it does not apply to travellers from England. But a traveller who reaches Egypt without a yellow fever certificate and subsequently wishes to go further south will find that no air line will allow him on a plane.

It is not safe to rely solely on the advice of officials of the air line concerned. I have on several occasions received inaccurate information confidently given in the best faith. A safer plan is to consult the consul or a recent traveller, but the only safe method for those who are intending to visit several countries is to keep inoculations up to date with the certificates properly authenticated. Even then it is by no means easy to discover what certificates will be accepted as being properly authenticated and up to date.

London W 1

HENRY TIDY

THE PSYCHIATRIC SOCIAL WORKER

SIR,—The following advertisement has appeared in the public press:

NOTTINGHAMSHIRE COUNTY COUNCIL PUBLIC HEALTH DEPT.

Appointment of three Female Mental Health Workers

Applications are invited from suitably experienced women for the above appointments to undertake various duties under the Mental Deficiency, Lunacy and Mental Treatment Acts. Preference will be given to duly qualified Psychiatric Social Workers or Candidates with a Diploma or Certificate in Social Science, and if so qualified the salary will be £370 + £20 p.a. – £530 p.a., commencing according to experience. For unqualified persons the salary would be £480 + £15 p.a. – £525 p.a. A motor travelling allowance and subsistence are also payable.

Application forms and further particulars are obtainable from the County Medical Officer, County Hall, Trent Bridge, Nottingham, to whom completed applications must be returned by July 24th, 1950.

K. TWEEDALE MEABY
Clerk to the County Council

The italics are mine.

It would, I think, be difficult to imagine anything better calculated to deter prospective entrants into this professional group or to disgust and alienate those present members who—against odds—have devotedly striven to maintain the present standard of professional integrity which we—their colleagues—have come to expect. I feel sure that this demigration of the professional standards of a small group within our greater professional body will cause not only you, Sir, but all liberal-minded members of the medical profession to request an immediate review of the status of the

ELECTRIC HEATING ELEMENT FOR THE LIMBS

SIR,—Last year I reported briefly that in rheumatoid arthritis the prolonged application to the lower half of the body of a large electric blanket at a temperature of 115°F, had a beneficial effect.¹ I pointed out that an electric blanket was a clumsy device for applying continuous heat, because it severely restricts leg movements. I also mentioned that an appliance used for this purpose should be shock proof and safeguarded against short circuiting and burning, and should have a temperature regulating mechanism.

For the last four months I have been using an appliance which appears to satisfy these conditions.

This appliance, depicted in the accompanying illustration, consists of a 20 ft ribbon containing a heating element of wire gauze mesh of stainless steel, 1½ in wide, which is embedded in insulating chemical resisting, plastic material. Flex leads connect the two element plugs to a 24 volt safety

transformer. The use of the low voltage removes any danger of electric shock. Two of these elements, one for each limb, can be applied at the same time, and both arms or legs can be treated. The skin is protected by a long woollen bedsock or crêpe bandage, and the element is wound round the limb from foot to mid thigh, or from wrist to shoulder. An insulating rectangular sheet of kapok of the correct length is then tied round the limb. The temperature of the element can be varied by switching the transformer from "high" through "medium" to "low," and also by making the coils wound round the limb overlap. Two layers of element will raise the temperature to 125°F when the transformer is on "high," whereas one layer will give a constant heat of 115°F of an equable distribution.

Four cases of rheumatoid arthritis have been treated with these elements continuously for 2–3 weeks, and the results agree with those achieved by the electric blanket method. One of these patients also had chronic severe psoriasis on the extensor surfaces of the limbs, and it was noted that the skin lesions improved considerably during the heat treatment. I therefore thought of trying the application of these elements to limbs affected by psoriasis, and I have now treated six patients suffering from chronic psoriasis who have failed to respond to other therapy.

In 3–4 days thick yellow scales, which peel off easily, form on the raised discs. New scales form until, after 7–14 days of treatment, no new scales develop and the skin of the affected area is no longer raised. It still looks red, but the covering layer is soft and smooth. The redness gradually fades from the centre to the periphery of the lesion, until the skin looks normal again. In three patients the psoriasis gradually reappeared, though in a less severe form. One patient with very large chronic lesions responded very well, but one month after he left hospital fresh lesions of the small, papular type developed, though the chronic psoriasis on his limbs had cleared up. Two patients had the elements applied to the

arms. One young woman, with large chronic discoid lesions on the abdomen, chest, and back, and additional lesions on the vulva which caused severe pruritus, was left wrapped in an electric blanket at a temperature of 115°F for two weeks with a typical response and well marked improvement in skin condition and the pruritus. It would be to try these elements in conjunction with various applications of proved value in psoriasis and also administration of calciferol by mouth.

Finally, two patients with chronic varicose ulcers which had resisted prolonged bed rest and various treatments, showed rapid healing of the ulcers when the elements were applied to the legs for two weeks.

I wish to thank Mr A. Dudley, of Windak Ltd., W. Poynton, Cheshire, for supplying me with the equipment in this work.

ERIC FRANKEL
Physician.

Wanstead Hospital London, E 11

HOSPITAL ACCOUNTS

SIR,—You do well to welcome (July 29) the improvement in the system of subjective accounting which has been introduced, but beware of the danger.

We are managed by laymen and by finance departments who do not understand patients' needs. They tend to be pleased when "So and So shows a low figure." They are not so concerned to make sure that he gets the same amount or quality, and that the patient is made as happy or got well as quickly.

Comparative accounting is good when it is not extravagant, it is dangerous when relied on without discrimination, for it may then encourage parsimony and depress treatment. Your editorial help will be needed to protect patients from the latter.

NOEL H. M. BAKER

UNDECYLINIC ACID IN PSORIASIS

SIR,—In an annotation¹ last year you drew attention to a report by Perlman² on the beneficial effect of psoriasis of undecylonic acid given by mouth. Seventeen patients had received this medication and he noted the disappearance of itching, improvement in affected nail, resolution of subacute cases, and great benefit to chronic sufferers. Later he and Milberg³ reported a larger series of cases in whom the effects were not so encouraging. Unfortunately, psoriasis is a common complaint and sufferers are ever ready to seize on new forms of treatment. As was to be expected, these American reports were widely publicised by the lay press, and St John's Hospital for Diseases of the Skin received considerable inquiries about "the new American treatment", so I decided to undertake comprehensive trials with this drug.

These trials were started in May, 1949, and continued over a twelve month period. At the outset some 100 patients were treated as inpatients at the Middlesex Hospital under Dr Ray Bettley, while the remainder were treated at a special outpatient clinic at St John's. The dosages and schedules varied from case to case but were on the lines advocated by Perlman. The patients were divided into three groups:

- 1 Receiving undecylonic acid capsules
- 2 Receiving capsules containing an inert oil which is identical in appearance with the "active" capsules and given in similar amounts
- 3 Receiving calciferol by mouth

As regards local applications, all the patients were treated in the same manner—i.e., those who had already been receiving local treatment when they were referred to the special clinic continued with the same routine, whereas those who had not started on any topical applications received the oral medication only. The following table summarises the results obtained.

1 *Lancet* 1949 i 575
2 Perlman H. H. *J. Amer. med. Ass.* 1949 139 441
3 Perlman H. H. Milberg I. L. *Ibid.* 1949 140 85

Notes and News

ILLING EXPENSES OF HOSPITAL PATIENTS

Reason for paying travelling expenses to and from hospital is to prevent hardship where patients have to go long or for long periods to get treatment. Hitherto, the patient's claim for his fare has depended solely on the frequency of his journey. Experience has shown that some patients have claimed and been paid their fare when they could themselves have met the cost without

Sept 1 there will therefore be a change in the rules. From that date the hospital will no longer be responsible for deciding whether it would cause a patient to pay his own fares and this assessment will be left to the National Assistance Board. A standard form of application will be supplied to hospitals which should be filled in by the patient and sent to his local office of the board. In an emergency it will usually take not less than 7 days for the board to complete the assessment. Except where the patient is already receiving assistance it will be usual for the board to visit his home. The assessment of the cost will be based on the cost of travelling by the cheapest public transport. The board will not allow for taxis, cabs, or where whose condition makes it impossible for them to use public transport will be able, as before, to be carried free by ambulance or sitting case car when this is recommended by a doctor or other appropriate person. Hospitals are asked to satisfy themselves that the patient really cannot travel alone, before authorising an escort for in the past the Ministry of Health thinks this concession has been much

abused. The scope of the new arrangements will not be so wide as in the past, but no patient really needing help to pay his fares should be prevented from getting hospital treatment.

THE NAPKINLESS AGE AGAIN

WHEN it comes of letting the male get into the kitchen, rather than the female, it has been revealed to women in one blinding flash of humanity has at last realised that washing 'napkins' is a mug's game. Hence in recent years various devices have been devised for fitting babies with destructible napkins made of cellulose.

An example recently put on the market is 'Babichou,' a container which ties round the waist, when it fits like a pair of neat bathing-drawers. It is lined with cambric, and has a pocket at either end to hold in place a strip of cellulose. The material is made from polyvinyl chloride, and is neither toxic nor irritant, as well as washable and durable. When the tapes at the waist are untied, the garment comes out flat and the soiled cellulose can thus be removed and discarded or—since it is soluble—flushed down the water-closet. A strip of cellulose can be fitted without taking the napkin right off. Babichou is made in various sizes, and is expensive—any size costs 4s 11d. The cellulose is a more serious item costing 1s 11d for a roll capable of giving 18 refills, or 2s 11d for a packet of 18 refills ready cut. 8 refills will not go far with a normal baby, and an average of 6-7s a week is too much for the poorer mother—who really needs help with the napkin problem.

Babichou is very similar to a garment described last year in the columns by Dr Quintin MacLaine.¹ Another variation on the theme also described last year by Dr C F McKhann and Mr George Brimont² of Oluo, has a boat-shaped container which allows the excreta and urine to drop away from the baby's skin, and so preserves him, they claim, from sore buttocks, eczema, ulceration, cystitis, and even gastro-enteritis caught from the hands of nurses who have changed another baby. Moreover the mother can empty the container without touching the baby, so preserving herself from contamination. These thoughtful advances in infant hygiene are all very well, but what we want now is something really cheap and easy way of an absorbent.

BROADCAST POSTGRADUATE LECTURES

SIR,—I read with interest your report last week (p. 239) on the postgraduate medical lecture given by Prof. Richard H. Freyberg from a New York wireless station on July 27. These lectures are an excellent innovation and one which would surely appeal to a great many doctors in this country. A series of specially selected lectures or discussions could be arranged either by the British Medical Association or the Royal Society of Medicine, and would be of very great help especially to medical men in the provinces who are unable to avail themselves readily of attendance at R.S.M. meetings, and so on. These lectures would bring to the microphone the voices of many we would like to hear, and many an excellent lecture which goes unread in *The Lancet* and *British Medical Journal* or other journals would be listened to with interest and profit.

I would suggest that these lectures should be given in the Third Programme at a convenient time for listening, for example 9.15 P.M.—10 P.M., and they could also be published in *The Lancet* or *B.M.J.* for future reference.

IVOR J. THOMAS

Obituary

ERNEST CRANMER HUGHES

M.CHIR. CAMB., F.R.C.S.

Mr. E. O. Hughes, whose death on July 28 we announced last week, was perhaps the most loved teacher Guy's has known in the last fifty years.

Born at Plymouth in 1878, he was educated at Marlborough and Clare College, Cambridge, where he obtained a first-class in the natural sciences tripos. In 1901 he entered the medical school at Guy's where he qualified three years later. After holding house-appointments he took his F.R.C.S. in 1906 and his M.Chir. a year later. In 1911 he was elected to the staff of Guy's as assistant surgeon. During the 1914-18 war he served in the R.A.M.C., and he was also consultant surgeon to the Queen Alexandra Military Hospital at Millbank. In 1932 he was promoted full surgeon at Guy's and in 1938 he nominally retired. But the following year he was working rather harder than ever as senior surgeon and teacher at the E.M.S. Pembury Hospital to which Guy's medical school was evacuated. He also continued to give a weekly teaching round at Guy's itself. He examined for the Universities of Cambridge and Birmingham and from 1930 till last year he was a member of the court of examiners of the Conjoint Board.

As a house-surgeon Hughes's chief had been Arbuthnot Lane, and as an assistant surgeon F. J. Steward. Throughout his life he retained the clean gentle technique of the one and the clinical soundness of the other. But it is as a teacher that he will be best remembered. His ward rounds were crowded occasions, with visitors from other hospitals who had come to hear him teach the bedrock principles which few could handle so well, for with his quick wit and humorous phrases he could deflate the pompous theory or the book-stuffed student and fix the simple truths in the minds of his hearers. When he retired W. H. O. wrote of "Joey" Hughes in *Guy's Hospital Gazette*: "He is seldom serious, yet withal so obviously earnest that his chaffing questions can never excuse a careless or flippant reply. He draws the whole class into the family circle, by appeals to each in turn, by interrogations pushed firmly but kindly to the verge of the third degree, and

then suddenly transferred to another whose seems to flag. Ridicule is alien to him; he suggests malice. The stories related of him are able, all illustrating the whimsical side of his; his ability to comfort a diffident houseman by the chance of a droll non sequitur, his power to all-pain or still the fears of an anxious patient, banter."

Mrs. Hughes survives him, with their daughter, their son, Dr. A. C. Hughes.

PETER LEWIS DANIEL

F.R.C.S.

Mr. Peter Daniel, consulting surgeon to the Hospital, died at his home at Checkenden on July 27 at the age of 79.

He was born and educated at Carmarthen, Charing Cross, where he held a Llewellyn. He qualified in 1898, and during the rest of his life except for a short period of postgraduate study in which he was associated with "The Cross." After house appointments there he took the F.R.C.S. in 1905 and in 1905 he was elected to the honorary staff. He was appointed lecturer in surgery at the Hospital. He was also on the staff of the Metropolitan and General Hospitals, and after he retired from Charing Cross in 1931 he continued his work at the Gordon Hospital. It was taken over by the National Health Service in 1948. During the late war he returned to help Charing Cross by working on the surgical side of the hospital at Ashridge. For many years he acted as referee to the Cremation Society.

One of the founders of the hospital Masonic Lodge, Charing Cross, he passed through the chair in its early days, and he also held office as treasurer for over 20 years. In the meantime he had attained London Council rank.

"Peter Daniel was the last survivor of the surgeons who were on the staff of the Charing Cross Hospital when I became a student there," writes N. L. "At that time the junior surgeons were also demonstrators in anatomy and it was in this capacity that the first met their future chiefs on the surgical side. Too, was the period before extreme specialisation had become the fashion, and so it is not surprising to find Daniel also held the post of pathologist and of the museum as well as being assistant in the department of the hospital."

"Many old students will recall with gratitude very practical teaching, without any 'high falutin' which they received from Peter. His surgery was not ostentatious or showy, but his judgment and opinion were sound to the core. Indeed, my chief impression of his character is of a man of great honesty of purpose, straightforward, with the courage of his convictions and with an abundance of common sense. For these reasons he was not only a very trustworthy surgeon, but also an excellent chairman and committee-man. With late Dr. William Hunter he was responsible for directing the attention of the profession to the importance of sepsis, especially in relation to certain forms of arthritis—a thesis which he developed in his book *Arthritis: Study of Inflammatory Diseases of Joints*. The ground to which Daniel belonged produced many fine, courteous surgeons who did magnificent work but abhorred publicity of any sort. He was true to type. Many old Charing Cross students, including me, must be thankful for their association with so fine a likeable a character."

Mr. Daniel is survived by his wife and their only son, Dr. P. M. Daniel.

Appointments

BARLOW, K. D. M.R.C.S., D.M.R. senior registrar in rd. White Lodge Hospital, Newmarket.

SHANNON, T. A. M.B. Lond. appointed factory doctor, district, Nottingham.

ITS OF INTRATHECAL TUBERCULIN STREPTOMYCIN IN TUBERCULOUS MENINGITIS

AN INTERIM REPORT

HONOR V SMITH

R L VOLLUM

I.D., BSc Lond

M A., DPhil Oxfd

*the Departments of Surgery and Bacteriology, Radcliffe
Infirmary, Oxford, and Military Hospital
(Head Injuries)*

NEEN November, 1946, and Jan 1, 1950, 84
s with tuberculous meningitis were treated at the
the Infirmary, Oxford, and the Military Hospital
ad Injuries, Wheatley. Of the 42 patients who
treatment before October, 1948, 22 died, giving
r all mortality rate of 52%. While treating these
we became rather better able to recognise some
signs of latent meningitis and were therefore in a
position to know when it was dangerous to stop
ent. In 1948 we decided to give longer courses
intramuscular and, in particular, of intrathecal
omycin in those cases in which the meningitis was
pamed by an overt military spread or by persistently
systemic tuberculosis. As a result the mortality
nce October, 1948, has been nearer 40% than 50%.
nce in almost all the fatal cases streptomycin was
up to the time of death, and since reports from other
s indicate that shortened or intermittent treat
is dangerous (Dubois et al 1949, MacCarthy and
1950), it is hard to see how results can be sub
ally improved by further modifications in régime

THREE PROBLEMS

en the experience gained in treating this series is
yed three problems stand out.
e first is. Why has it been possible to cure only
50% of patients?
e second is the extreme difficulty of making an
ate prognosis in the individual case. The only
rs that we have found to be of prognostic significance
he outset of treatment have been the state of
ousness and the presence or absence of focal
ological signs, and these only in their crudest terms.
although most of those patients have recovered
were fully conscious and rational when first seen,
w have died, while of those who were 'deeply
orous or delirious, a few have lived. Nor is the
ulty confined to the first few days of treatment.
asionally a patient may make a dramatic improve
t from the outset, but as a rule he remains critically ill
any weeks (Smith, Vollum, and Cairns 1948, Lincoln
Kirmse 1949). During this time he is drowsy,
hetic, and incontinent, or frankly demented. He
its frequently, his appetite is poor, and he persistently
weight (Cairns and Taylor 1949, case 4). Typically
protein in the cerebrospinal fluid (C.S.F.) rises, the
ure often falls, and spinal block may threaten
pervene, while new focal neurological signs may
ar. all evidence that though the infection is sup
ed it is not fully controlled. Then, in successful
, a sustained improvement slowly becomes apparent
at last it is no longer too rash to say that the patient
robably recover. In fatal cases the period of dead-
may be prolonged for months, but ultimately it
hes only too obvious that the patient is losing
ld more and more rapidly until finally he dies,
with a terminal rise in intracranial pressure.
re is one exception to this difficulty in prognosis
s the condition of decerebrate rigidity (Wilson 1920)
the patient has not only become comatose, but
also developed tonic extensor rigidity with hyper

pronation of the forearms, opisthotonos, tonic spasms,
and chewing and sucking movements (fig 1), we have
never seen any improvement whatever, and most
patients died in a matter of days (usually three to
twenty one). We have accordingly found the decere
brate state the only absolute indication for stopping
treatment.

It is easy to say that those patients recover whose
treatment is begun early in the illness, while the others
die, but it has unfortunately proved impossible as a
rule to tell what stage the disease has reached when the
patients first come for treatment. Apart from the
decerebrate state, which is almost a terminal event,
there is no finding, either in the clinical picture or in
the C.S.F., which has not been seen in successful as well as
unsuccessful cases.

The third problem is closely allied to the other two.
In fatal cases the most constant and characteristic
necropsy finding is the thick collar of exudate surround
ing the mid brain (Daniel 1949). On microscopy, nests
of organisms can be found embedded in this exudate,
which protects them from the streptomycin in the
blood and C.S.F., and thus enables them to keep the
inflammation smouldering (Cairns 1949). In those
cases in which spinal block develops, the spinal sub
arachnoid space is found choked with similar exudate.
Many of the effects of the basal exudate are easily
recognisable clinically (Smith
and Daniel 1947,
Smith, Vollum,
and Cairns 1948)
and have been
frequently seen in
successful as well
as in fatal
cases. Moreover
it is possible
for a patient to
have a complete
spinal block for
months and yet
to recover, and
for the block
to disappear.
A considerable
degree of reso
lution of this
exudate must
therefore be
possible. What is
it then that
determines
whether the
exudate will
resolve or whether
it will persist and
increase to death?

It would seem
that there is some
important factor
other than the
"drug-organism relationship" that we have been unable
to recognise, far less to assess. This unknown factor
is presumably related to the host response, and a
possible clue to its nature has been given by the
behaviour of the cells and protein in the C.S.F. in cases
under treatment with streptomycin.

C.S.F. CHANGES DURING STREPTOMYCIN TREATMENT

Ever since we first began this study it has been our
practice to combine the intramuscular administration of
streptomycin with long uninterrupted courses of daily

Fig 1—Complete decerebrate rigidity in
tuberculous meningitis unsuccessfully
treated with streptomycin

Postgraduate diplomas and diplomas of membership were granted to those named in our issue of Aug 5 (pp 230 and 240). A diploma of membership was also granted to K M McIndyean.

Epsom College

The 97th annual general meeting of the governors was held on July 7, with Dr Harold Spitta, the chairman of the council, in the chair. He reported that the progress of the school continued to be most satisfactory. Rises in costs had forced the council to raise the fees from Michaelmas 1950, and to make a charge for stationery and the use of books. The council intended to appeal for funds with which to make lasting improvements to the school in commemoration of the centenary of the college and its Royal Medical Foundation.

Ophthalmology Congress

The Fourth Pan American Congress on Ophthalmology is to be held in Mexico City from Jan 6 to 12, 1952.

The Scientific Basis of Medicine

A course of lectures on this subject is to be given at 5.30 p.m. on Tuesdays and Thursdays from October to March at the London School of Hygiene, Keppel Street, WC1. The course has been arranged by the British Postgraduate Medical Federation and admission will be free without ticket. Sir Henry Dale, O.M., will open the course on Oct 10 with a lecture on Scientific Method in Medical Research.

Payment for Board and Lodging in Hospital

At a meeting of the North West Metropolitan Regional Hospital Board on July 10, Prof H W C Vines, said that the Minister of Health's decision to limit expenditure must adversely affect the development of the hospital service. After referring to the high cost of provisions, he questioned the statutory authority for providing food without charge to hospital inpatients. He thought that a charge should be made and that the money thus saved should be used for developing the service.

World Federation for Mental Health

The third annual meeting of the federation will be held in Paris from Aug 30 to Sept 7. About 200 delegates representing 22 countries will be attending. The discussions at the meeting have been designed to lead up to the work of the next International Congress on Mental Health in 1951. They are concerned with mental health in education, in industry, and among transplanted and homeless people and with leadership and authority in local communities. The government of Mexico has invited the International Congress to hold its meeting there in December 1951.

Use of Toxic Chemicals in Agriculture

The Minister of Agriculture has set up a working party "to make recommendations for the promotion of the safety of workers in the agricultural use of substances which are toxic or harmful to human beings, and in particular to advise on the recommendations on this subject made in the report of the Gowers Committee on health, safety, and welfare in non industrial employment." Last year the Gowers Committee recommended that the Minister should be given powers to prescribe by regulations the fertilisers sprays and other chemicals for the use of which the supply and wearing of protective clothing should be made compulsory.

Conference on Maternity and Child Welfare

Next year the annual conference on maternity and child welfare will be held on June 20, 21, and 22, at Finsbury Euston Road, London, NW1.

London County Medical Society

The next clinical meeting of this society will be at St Stephen's Hospital, Fulham Road, Chelsea, on Thursday, Sept 14, at 3 p.m. Inquiries should be made of Mr J Gabe, F.R.C.S., St Alfege's Hospital, Greenwich.

Leverhulme Grant

A Leverhulme research grant has been awarded to C W Dixon, lecturer and chief assistant in the department of preventive medicine and public health in the University of Leeds, for his work on the epidemiology of smallpox and the control of variola minor.

Plastic Lenses

The Minister of Health has decided to include bifocal and lenticular plastic lenses in the range of glasses for which the patient contributes. The new lenses will be supplied on request when bifocal lenses are prescribed. Lenticular lenses are necessary for certain types of vision.

Royal Institute of Public Health and Hygiene

At 28, Portland Place, London, W1, on Wednesday, Sept 20, at 3 p.m. Dr Nadia du Bouchet, head of the anaesthetic centre of the Broussais Hospital, Paris, will give the Bengué lecture on Modern Anaesthesia in France and its Developments Related to Cardiac Surgery.

Aviation Award

The Raymond F Longacre award for 1949 has been presented to Sir Charles Symonds by the Aero Medical Association of America. This award is given annually to the person who has made the most important contribution to the development of aviation medicine, including the development of aptitude tests for flying.

American Public Health Association

The 78th annual meeting of the association and meeting of the 32 related public health organisations will be held in St. Louis, Missouri from Oct 30 to Nov 3, under the presidency of Dr Lowell J Reed, vice president of the School of Public Health and Public Health, Johns Hopkins University. Information may be had from Dr Reginald M. Atkinson, executive secretary of the association, 1700, Broadway, New York 19, N.Y.

CORRIGENDUM *Dimercaprol in Acute Lead Poisoning*
The doses of dimercaprol given by Dr Bastrup (July 29, p 171) were 0.1 g (not 0.1 mg).

Births, Marriages, and Deaths

BIRTHS

BROWN—On July 30, the wife of Captain J A W Brown, —a daughter.
GABE—On July 31, in London the wife of Mr Joel Gabe —a daughter.
HARMAN—On July 30 in London the wife of Dr J B H —a daughter.
HOLLINGS—On July 29, at Kingston the wife of Dr Brian —a daughter.
KNOWLEDEN—On July 29 at Beckenham the wife of J Knowelden —a son.
MARTIN—On July 27 at Worthing the wife of Mr Kenneth —a daughter.
MOON—On July 29 in London the wife of Dr A J Moon —a daughter.
ROWLANDSON—On July 27 at Cambridge, the wife of Mr Rowlandson, F.R.C.S. —a daughter.

MARRIAGES

BORN—FLOWDEN WARDLAW—On July 27 in Edinburgh Victor Rudolf Born M.B. to Wilfrida Ann Flowden V.
BOTTOMLEY—ISHWOOD—On July 29 Frank Bottomley to Fild Ruth Isherwood.
BOWEN—DAVIS—On July 29 in London David Aubrey Bowen M.B. to Joan Rosemary Davis.
DYER—TAYLOR—On July 29 in London Haydon Dyer to Audrey Dorothy Taylor.
LAWCOCK—TUNBY—On July 28, at Ruislip John Dixon M.B. to Julia Tubby.

DEATHS

AUDLAND—On July 31 William Edward Audland M.B.E. aged 90.
BANKS—On Aug 1 John Herbert Banks M.R.C.S. aged 70.
BRIMS—On July 31 Donald James Brims M.R.C.S.
DANIEL—On July 28 Chickenden Oxon Peter Daniel.
HUGHES—On July 28 at Pembury Ernest Cranmer.
JONES—On July 30 in London Ernest Thomas M.B. aged 70.

ious by giving a third, or even a course of intra injections after five infection is lled (fig 4), as we have never hese fluctuations es in which a en diagnosis of ulous meningitis nade and intra streptomycin was ore given unneces (fig 5), and se they are not in the other es of meningitis uch the infecting asm is sensitive to tomycin—e g, *ophilus influenza*—

PROTHESIS TESTED

our experience ore these changes ie CSF are specific tuberculous menin- under treatment streptomycin This vation, together the finding that appear about the e that organisms are ppearing from the F suggests that they ht be caused by the ration and accumu on of bacterial break n products—i e., of reulin—into the e of the sensitised ent

n attempt has been made to test this supposition three ways

If it was true, then tuberculin should provoke se in cells and protein when introduced into the ca of someone sensitised to tuberculoprotein—as wn for example by a positive Mantoux test—but when given intrathecally to someone in whom the atoux test was negative This experiment has now n done many times in subjects in whom the CSF normal in all respects and who were not suffering a tuberculosis.

We have used the purified protein derivative of reulin (P.P.D.)² The results are clear-cut. Lumbar ctions of 0.75–7.5 μ g P.P.D. have been given to 5 ects in whom the Mantoux test was negative to ml or 1/100. In no case has there been any cal disturbance, and the cellular and protein response been negligible (fig 6)

y contrast, when given in doses of 0.00375–3.75 μ g subjects in whom the skin gave a moderately brisk onse to 0.1 ml or 1/100–1/1000, there has always a marked response clinically and in the CSF

7) The clinical response consists in fever and iting. The fever usually reaches its maximum re to twenty four hours after the injection and

en streptomycin is introduced into the normal theca a cellular reaction is occasionally seen and is accompanied by nausea, vertigo and drowsiness. More information is needed bout this

P.P.D. used has been the standard preparation supplied by the Ministry of Agriculture and Fisheries Veterinary Laboratory, Weybridge. It was used in order to avoid possible non-specific effects caused by the glycerin and other impurities present in Old Tuberculin

Fig 4—Similar graph in a successful case of tuberculous meningitis complicated by an overt millary spread. Typical spikes in cells and protein are seen during the first course of intrathecal streptomycin but are not reproduced during the subsequent intrathecal courses. The irregular disturbances in the protein curve during the second intrathecal course paralleled the number of red blood cells in the CSF and resulted from traumatic punctures (Case 67)

subsides within two to three days. The cell-count rises to 300–3000 cells per cmm and on the first day usually shows 40–80% polymorphonuclears. Cultures for pyogenic organisms have invariably been sterile. The count then falls for the next three to four days, and then usually rises again. After the first two days practically all the cells are lymphocytes. The protein also rises to 80–400 mg per 100 ml, and then slowly falls, though it too may rise again slightly with the second, lymphocytic, peak in the cell count. From then on the daily cell counts fluctuate, but on the whole the curve falls, though it may be many weeks before the cell-count returns to normal. During the early days of the reaction many of the cell and protein counts are typical of those seen in tuberculous meningitis, and the CSF samples show the classical “cobweb” clot. The process is however quite benign. The injections have been repeated several times in different subjects and also several times in the same subject, and the clinical and meningeal disturbances can be produced at will (fig 8)

2 The second approach was to collect CSF from a patient with tuberculous meningitis under treatment with streptomycin at a time when the cell and protein fluctuations were appearing, and, after Seitz filtration, to inject it intradermally into a tuberculin sensitised subject. This has been done four times with uniformly negative results. However, CSF collected twenty four hours after an intrathecal injection of P.P.D., at the time when the clinical disturbance was at its height and the meningeal reaction was beginning, also gave entirely negative results. Either the intradermal test is not sensitive enough to detect the minute amounts

intrathecal injections. At each puncture a sample of C.S.F. is collected, the cell and protein content is estimated, smears are examined for tubercle bacilli, and cultures are set up. The results of these daily examinations of the C.S.F. are set out as a graph and in our series a fairly definite pattern can be distinguished (fig 2).

In successful cases the positive films and cultures become less numerous until finally the organisms disappear altogether. This usually takes from two to four weeks, but not infrequently tubercle bacilli may reappear in one or two later specimens of fluid.

In the great majority of cases the cell counts show remarkable day-to-day fluctuations (Cairns and Taylor 1949). At the peaks of these fluctuations the total cell-counts are of the order of 600 to 1600 per c.mm.—i.e., well above the range seen in the untreated disease (Smith and Daniel 1947). Typically these high spikes of cells contain 60–90% of polymorphonuclear leucocytes. The fluctuations usually appear between the fourth and fourteenth days of treatment, they may only occur once or twice or they may persist for weeks. In successful cases the fluctuations ultimately flatten out and the cell curve begins to fall steadily. In those cases however where an isolated positive film or culture is obtained late in treatment, one or two solitary spikes of cells may reappear about the same time as the organisms (fig 12). Occasionally, too, their reappearance coincides with the development of new focal neurological signs.

The protein curve also tends to fluctuate from day to

day during the first few weeks of intrathecal streptomycin, when the abrupt peaks may be 100–200, previous levels. They occur at about the same time the high spikes of cells, though often not on the same day. Apart from day to day fluctuations, the protein content usually rises for at least six weeks. In successful cases the fluctuations ultimately disappear, persistent rise stops and the curve first flattens out and finally falls.

In unsuccessful cases the organisms either die, or, if films and cultures do become negative, tubercle bacilli can be found post mortem in the meninges. Usually the fluctuations in the cells and protein content flatten out, but the protein does not fall down to the level seen in the successful case (fig 3).

The cause of the high and fluctuating cell counts of the peaks in the protein content is obscure. They are not due to secondary infection, because the pyogenic organisms have always been sterile. They are almost certainly not due to mere irritation by intrathecal streptomycin, because in many cases the organisms die down and disappear even though the intrathecal injections of streptomycin are still being given (fig 2), because it has proved impossible to reproduce.

1 Three cases in this series have been complicated by a secondary infection due to *Streptococcus faecalis*, *Streptococcus pneumoniae*, and *Staphylococcus aureus* respectively. Both the clinical picture and the C.S.F. findings were profoundly different from those under discussion.

Fig 2—Graph showing C.S.F. changes, temperature, weight, and treatment in an uncomplicated case of tuberculous meningitis successfully treated. Note the high irregular spikes in the cell and protein curves. These spikes begin about the 10th day of treatment when organisms are disappearing from the C.S.F. In this case they flatten out well before the intrathecal injections are stopped and at about the same time that the temperature settles. (Case 48)

Fig 3—Similar graph to fig 2 in a complicated case. Note the completed of spikes in the cell and protein curves although the intrathecal injections of streptomycin are given daily up to the death. Post mortem intense staining clusters of tubercle bacilli including the cisterna ambiens (fig 2). (Case 39)

—Similar graph to fig 6 in a patient without meningitis who lived 0.75 µg PPD by intrathecal injection but in whom the Mantoux test was positive to 0.1 ml O.T. 1/1000. Note sharp rise in temperature accompanied by brisk pleocytosis and rise in protein.

ed that the lateral ventricles lay within about 2 cm of the scalp. All four limbs were spastic and paralysed and tightly flexed across his body. His pupils were dilated fixed to light and although he would still respond to a loud bellowing cry, there was no response whatever to visual stimulus.

Once to Tuberculin

there was obviously nothing to lose, it was thought feasible to observe the effects of intrathecal injections of

At this time an intradermal injection of 0.1 ml 1/1000 gave a flare and weal approximately 2 cm in diameter. As no lumbar fluid could be obtained, it was decided to make serial observations of cisternal C.S.F. Accordingly two successive samples of cisternal fluid were examined (cells 20–22 per c.mm., protein 100–82 mg per 100 ml) and then 20.75 µg PPD was injected into the lateral ventricle. The same night the temperature rose slightly, the tension in the fontanelle increased, and the child vomited frequently. Still more alarming upper limbs became extended and hyperpronated in the classical decerebrate state. The clinical picture, however though severe, was short lived, and although the temperature did not begin to fall for three days there was no immediate anxiety about the child for the first twenty-four hours.

The C.S.F. response was rather more delayed. Nine hours after the injection the cisternal protein had risen from 82 to 240 mg per 100 ml, and 1100 cells per c.mm. had appeared although all recent cultures had apparently been aseptatic. The total cell count had however not increased significantly, though a few polymorphonuclear cells had appeared (total 29 per c.mm., 15 polymorphonuclear compared to 22 per c.mm., 6 polymorphonuclear at the time of injection). After another six hours (twenty-five hours after injection) the protein and cells had again risen (282 mg per 100 ml and 30 per c.mm. respectively) while the white-cell count was now 74 per c.mm., 46 of which were polymorphonuclear. The white cells and protein continued to rise irregularly as shown in fig 8, reaching their maximum (150 per c.mm. and 700 mg per 100 ml) respectively ten days after the injection.

On June 30 and July 1 cisternal injections of an emulsion preparation of streptomycin were given. The same preparation was subsequently tried exhaustively in another case of tuberculous meningitis and without any evidence—clinical, radiological, or at autopsy—of resolution of the exudate. The effect of these injections was quite different from that produced by P.P.D. There was no clinical reaction whatever. The cells rose within twenty-four hours to 660 per c.mm. (78% polymorphonuclear) to fall steadily and anent during the next two days. There was no

significant increase in either the red cells or protein content. This response is typical of a mild non-specific chemical meningitis.

On July 10 the first of several further injections of P.P.D. was given, but into the cisterna magna instead of the ventricle. As the clinical reaction to the first injection had been so alarming, only one tenth of the original amount was given (0.75 µg). An exactly similar though milder response was seen both clinically and in the C.S.F. The dosage was gradually increased and good evidence was obtained of a falling response, as shown in fig 9. There was also evidence that the sensitivity of the patient's skin was decreasing and by the end of September 0.015 mg P.P.D. (approximately equivalent to 0.2 ml O.T. 1/1000) produced a flare only about 2 cm in diameter.

Recovery

But to everyone's astonishment as the weeks passed, it became apparent that the child was improving. The vomiting stopped except during the twenty-four hours immediately following an injection of P.P.D., while after each reaction the temperature would fall to a new low level. By the end of August 1949, he was gaining weight rapidly, he was much less irritable and was beginning to play with his toys. The dusky brown tinge of his skin had nearly gone, he was losing the downy hair which had covered his body, and the pressure sores had healed. His head was much less retracted and no trace of the extensor posture had been seen since the reaction to the first injection of P.P.D. Now that he was moving his limbs, a right hemiparesis was obvious. Everyone was, however, still convinced the child was blind. A photograph taken at this time (fig 10) illustrates these points, but also indicates how bad the child's condition had been when at its worst, since all observers were agreed that by now he was very much better.

The injections of P.P.D. were continued until October and except for the reactions which followed each one, and which were now quite trivial, the child improved steadily. By the

Fig 8—Cellular, protein and febrile response in a patient without meningitis who received five times the dose shown in figs. 6 and 7, i.e., 3.75 µg P.P.D. by intrathecal injection. Mantoux test positive to 0.1 ml. O.T. 1/1000. Injection repeated after many weeks. Both injections caused a dramatic rise in cells and protein accompanied by fever and vomiting.

of tuberculin present, or the tuberculin may be adsorbed on the cells and thus removed from the filtrate

3 The third approach was to choose a patient in whom the regular treatment with streptomycin had obviously failed and in whom the cell fluctuations had disappeared, and to find out whether an intrathecal injection of PPD would reproduce the cell and protein fluctuations seen earlier in the illness. As it chanced we had two such patients under our care during the summer of 1949. The effects of the intrathecal injections of PPD and the subsequent events merit a full description.

FIRST CASE (fig 9)

A boy, aged 1 year 10 months, was admitted to Peppard Sanatorium on April 1, 1949, under the care of Dr Harley Stevens. He had a very strong family history of tuberculosis, his maternal uncle had died of pulmonary tuberculosis, and a first cousin of tuberculous meningitis. A maternal aunt was undergoing sanatorium treatment and his mother has since been admitted to a sanatorium, both with pulmonary tuberculosis. The patient himself had been quite well until seven weeks before admission, when he developed measles, from which he never seemed to recover. He had a persistent fever, grew thinner and more apathetic, and was very constipated. At the end of March radiography of chest showed diffuse mottling through both lung fields, shortly afterwards his neck was found to be stiff and he was sent into hospital with a diagnosis of miliary tuberculosis and tuberculous meningitis.

Course of Illness

On admission he was ill and wasted. His head looked too large for his body, and although he was nearly 2 years old the anterior fontanelle was widely open though not unduly tense. He was very drowsy and apathetic and yet irritable. When undisturbed he would lie quietly, but he would cry miserably when touched or moved. Movements of his eyes seemed to be full, and he moved his limbs normally. The tendon reflexes were within normal limits, but both plantar reflexes were extensor. Lumbar puncture yielded fluid under a very high pressure containing 100 cells per c mm, with 162 mg protein and 680 mg chlorides per 100 ml (sugar not estimated). Scanty acid fast bacilli were seen on smears.

Fig 5—Similar graph in a case of probable polio-encephalitis in which a mistaken diagnosis of tuberculous meningitis was made and treatment with intramuscular and intrathecal streptomycin was therefore begun. Note the absence of spikes of cells and protein which contrasts strongly with the curves in figs 2 and 4.

Treatment with streptomycin was begun immediately the child received a daily lumbar injection of 50 mg 0.25 g twice daily by intramuscular injection. In the first two weeks he grew a little better, the lessened, he took fluids well by mouth, he did not his nutrition improved slightly. During the third treatment the improvement flagged, lumbar puncture difficult, and the c s r was bloodstained. During week he grew worse, he vomited frequently and stiffness increased. Lumbar puncture now yielded containing 130 cells per c mm, with protein 177 mg, 655 mg and sugar 43 mg per 100 ml. Acid fast still present on the direct smears.

On May 4, 1949, the child was transferred to the Infirmary, Oxford, because it was feared that he was having a spinal block and neurosurgical intervention was indicated. He was now extremely ill and his skin was with diffuse brown pigmentation. Though the reference of his head was within the limits of normal, fontanelle measured 2.5 by 2 cm, and radiograph of skull showed slight expansion of the sagittal suture. There was gross neck stiffness with considerable head retraction. When left alone he would usually lie quietly curled up on side with all four limbs flexed, but from time to time he would utter a loud cry like an animal. There was constant sucking, and grinding of the teeth. The fundi were he would follow objects with his eyes, and the pupils,

Fig 6—Cell and protein content and temperature following the thecal injection of 0.75µg PPD in a patient without meninges and in whom the Mantoux test was negative to 6.1 ml OT. No disturbance of temperature or protein content cellular negligible.

dilated, reacted briskly to light. There was a mild facial weakness and possibly some weakness of his right limb, but he was so reluctant to move that it was hard sure of this. The spleen was easily palpable, and radiograph of the chest still showed marked miliary changes. Gastric washings grew tubercle bacilli on culture.

Lumbar puncture was performed in the three lower lumbar spaces and confirmed the impression of incipient spinal block. The c s r was heavily mixed with old blood and could be obtained (with great difficulty) by aspiration. According to bilateral frontal burr holes were made to give access to lateral ventricles, and a course of intraventricular injection (50 mg daily) of streptomycin was begun. The first 12 of fluid obtained contained 43 cells per c mm and 12 protein per 100 ml, and tubercle bacilli were grown on culture. As vomiting was persistent, an intravenous drip was set up, physiological saline was given first and blood later.

Despite these measures the child grew worse. During next nine days the protein in the lumbar fluid rose to 1 g per 100 ml and thereafter all attempts at lumbar puncture resulted in dry taps. The protein in the ventricular fluid also rose to 500 mg per 100 ml (fig 9). He was feverish, the wasting, head retraction, and hydrocephalus all increased until by the middle of June his condition was hopeless and the intrathecal injections of streptomycin accordingly abandoned. This was the more difficult in that X ray films of the chest showed slight improvement, and cultures of gastric washings were now negative.

At this time his head was so retracted that it rested on his shoulders. He was dreadfully wasted, and in spite of being turned frequently he had developed several ulcers. His skin was deeply pigmented and covered long lanugo like hair. The fontanelle was full and bi-radiography of the skull showed increased expansion of sutures and on one recent occasion c s r had leaked taneously from one of the burr holes. Ventricular puncture

Fig 10

Fig 11

0—(Case 1) Photograph taken two months after first intrathecal injection of D. The enlargement of the head and the fixed flexion attitude of the legs are still present but the head-retraction though still present has lessened the pressure over the left trochanter has healed he is losing the downy hair which had covered his whole body, and can move his left arm.

11—(Case 1) Photograph taken a year later. Unfortunately this photograph was reversed and it is in fact the right hand—the one previously paralysed—that the child has lifted to its mouth—H.S.

streptomycin was given into left ventricle. After this the child grew lighter next day he obeyed simple commands and the following day he began to walk.

For three months he slowly improved. For weeks he was intensely irritable but he gradually grew more rational, though he remained emotionally unstable. By the middle of June he had gained about 6 lb weight and had no abnormal neurological signs. He still looked thin and frail and psychometric tests suggested about a 20% loss in function.

The behaviour of the cells and protein in the C.S.F. was typical of the first three weeks of treatment (maximal rise 165 to 600 per c mm in twenty hours), and the protein rose to 400-500 mg per 100 ml. The cell fluctuations flattened out and the protein then stopped rising and the cell fluctuations flattened out. No bacilli were present on films and culture for six consecutive days and then disappeared. During the sixth week of treatment the protein content began to fluctuate almost daily (maximal rise from 420 to 740 mg per 100 ml in twenty four hours) and though less frequent fluctuations reappeared in the cell curve on the forty ninth day of treatment.

ment acid fast bacilli were once again seen on smears and on the fiftieth day the cells shot up to 950 per c mm (32% polymorphonuclears). The daily intrathecal injections were therefore continued for another eight weeks from this time.

At the end of June it was decided to give him a rest from the intrathecal injections, but, in view of the severe chest lesion, to treat him with the prolonged régime we were then using in cases where the meningitis was accompanied by an overt military spread (Carns, Smith, and Vollum 1950). The decision to withhold the intrathecal injections even temporarily was taken with some trepidation for, though the C.S.F. fulfilled the criteria laid down for stopping treatment (Carns, Smith, and Vollum 1950), and though his clinical condition was reasonably good, he was no longer gaining weight and he still had a low grade fever. We were also influenced in favour of giving him a rest by the fact that after 105 consecutive intrathecal injections he had become extremely intolerant of his lumbar punctures, which were by now a severe ordeal for all concerned.

But after about two weeks it became only too apparent that the boy was losing ground. During this time the left knee became swollen and painful, and our orthopaedic colleagues had no hesitation in making a diagnosis of tuberculous arthritis. The joint was immobilised by a plaster splint but remained as big as ever. After seventeen days the intrathecal injections were begun again, but the boy grew worse increasingly rapidly. He vomited frequently and grew dreadfully wasted, his neck and back became extremely stiff, he lay in a light stupor all day but, when asked, he complained of severe headache. The pressure in the C.S.F. rose to over 300 mm H₂O and was only controlled for a few hours by decompressive lumbar taps. No further tubercle bacilli were obtained on film or culture.

Fig 12—Graphic representation of the course of the illness in case 2. For explanation see text.

middle of September it seemed that his sight was returning and by the beginning of October he could obviously see quite well. He was now a well covered, rosy little boy, playing happily with his toys and beginning to talk, though still resentful of being moved. Movements of both arms were normal but his legs were still very stiff and perpetually flexed. He could move his feet but not the knees or hips. There was a well maintained clonus at the right ankle, but both plantars were now flexor. X ray appearances in the chest were within normal limits.

During November, after six months of persistently dry taps, lumbar puncture once more yielded C.S.F., though the flow was still extremely slow. The cisternal C.S.F. was by now approaching normal. Radiography of the skull showed that the sutures were normal and the fontanelle nearly closed. By January he could feed himself and could pull himself up on to his knees. By February he could stand and in March he learnt clean habits.

By April 1, 1950, just one year after treatment was begun, he was a fat healthy looking little boy who could walk holding on to someone's hand (fig 11). There was a mild flexion contracture of the right hip and knee, a legacy of the old hemiplegia, but except for the unsteadiness of gait there were no abnormal neurological signs. There was free flow of C.S.F. on lumbar puncture and both the lumbar and cisternal fluids were normal in all respects (protein 28 mg per 100 ml., 3 cells per c.mm.). His vocabulary, though still very limited, was increasing, and psychometric tests confirmed the impression that he was rapidly making up the ground he had lost during his long and serious illness.

This child, who had a proved tuberculous complicated by an overt miliary spread, worse in spite of intensive treatment with given by the lumbar, ventricular, and routes. When his condition appeared intrathecal streptomycin was withheld amounts of P.P.D. were injected first into, and then into the cisterna magna in order effect this had on the C.S.F. These injections produced the expected rise in the cell and of the C.S.F. but also a totally unforeseen element. We therefore sought opportunity to injections of P.P.D. in another case in which streptomycin had failed.

SECOND CASE (fig 12)

A boy of 17½ years was admitted to the P.C. on March 25, 1949, under the care of Dr P.C. for an attack of bronchitis when he was 3, his past uneventful and there was no family history of and no history of contact. He had been until a week before admission, when he developed cold in the head and a little later began to vomit complain of headache. The headache and rapidly worse, and for the last four days before had vomited everything he had swallowed. He increasingly drowsy.

Course of Illness

On admission he was deeply stuporous, but

roused show that he interference pale and thin, his was very stiff, and Kernig's sign was positive. Apart from a slight facial weakness there were no focal neurological signs. Lumbar fluid under a of 300 mm. H₂O containing 120 cells c.mm., with protein mg, chlorides 5.0 and sugar 47 mg 100 ml. Acid fast were seen on the smear, tubercle bacilli were grown on culture and guinea pig inoculation was positive. Radiography showed an extensive infiltrative of the left mid zone enlargement of the glands.

On March 25, 1949 treatment was 1 g of streptomycin given twice daily intramuscularly and 100 mg daily by lumbar injection. During next few days he was worse, and by March 28 was comatose, then responding to stimuli. Because of deterioration both tricles were drained through bilateral burr holes. Both capacious and abnormally placed, the pressure was 40 mm. H₂O and tubercle bacilli were seen on smears from ventricular fluid. daily intrathecal 1 g.

Fig 9—Graphic representation of the course of the illness in case 1. For explanation see text.

and injection the axillary temperature rose to 106 F. This minute dose caused no significant rise in cells. At 25 the intrathecal streptomycin was again begun and of the persistently positive films. Three days later the dose of P.P.D. was increased to 1.25 µg and from then on every injection was followed not only by an exacerbation of signs and symptoms but by a sharp rise in the cells often in the protein (fig 15).

The child remained extremely intolerant of the intrathecal P.P.D., which even in minute doses would cause an exacerbation of the opisthotonus and an access of fits. As the weeks passed, however, it became apparent that each reaction was followed by slight improvement. Temperature settled, the depth of coma lightened, crying ceased, and coughing all returned, the opisthotonus disappeared, and the extensor posture of the limbs finally replaced by one of flexion. Though the child very thin, she never showed the extreme wasting associated with chronic meningitis and all the pressure sores except one which had become heavily infected with *domona pyocyanea*. Most surprising of all, the cerebrospinal fluid remained within normal limits during the whole illness, and the obstructive hydrocephalus, hitherto invariably in decerebrate rigidity, never developed. Sight, as judged by the persistence of a brisk menace reflex, was preserved throughout. The Mantoux test became negative to 0.1 ml 1/10.

At this stage, however, the improvement stopped. It seemed therefore that, though the meningitis was controlled, the widespread cerebral infarction, which was precluded any useful recovery, must have taken place at the time the decerebrate state appeared. Ventriculography, which was performed on the 170th day of treatment, supported this conclusion. The whole ventricular system was grossly but symmetrically enlarged while the sutures were all within normal limits. After this procedure the child's chest became very bubbly and she died of inanition twenty-five weeks after treatment was begun.

Fig 16—Drawing of brain cut through the cisterna ambiens showing the dense exudate hitherto invariably seen in cases showing the decerebrate picture. The patient became decerebrate and died after five months' treatment with streptomycin.

Post mortem Findings

The skull was normal, with no spreading of the sutures. The meninges at the base of the brain were thickened but macroscopically there was no exudate in the cisterna ambiens or Sylvian fissures (figs 16 and 17). There was widespread bilateral infarction of the basal ganglia and external and internal capsules. These infarcts were old and shrunken and appeared to correspond well in time with the onset of the decerebration. The severe ventricular enlargement was secondary to the gross destruction of brain tissue. There was a small, firmly encapsulated tuberculoma in the right Sylvian fissure which may well have acted as a 'Rich's focus' (Rich and McCordock 1933, Rich 1944) (fig 18). In the lungs there was a well calcified primary complex, but no sign of tuberculosis elsewhere.

Microscopic examination showed several small foci of tuberculous granulation tissue in the interpeduncular region and a larger focus lying beside the left optic nerve. In many places there was cuffing of the penetrating vessels of the brain with chronic inflammatory cells and macrophages. The white matter of the cerebral hemispheres and cerebellum showed microcystic spaces and small focal collections of fat granule cells the terminal result of focal demyelination. There was a fairly widespread granular ependymitis. The basal ganglia showed gross damage with very numerous microcystic spaces and fat granule cells.

This case is unique in our experience in that the child not only lived for twenty-three weeks after developing the full decerebrate state but showed a sustained objective improvement, though this never amounted to a useful recovery. The necropsy findings were also unique, for in every other case in which the decerebrate state developed the cisterna ambiens was invariably choked with exudate of almost cartilaginous density (fig 16). Indeed this has with one exception, been a constant finding in all the cases in this series that have come to necropsy.

Fig 15—Graphic representation of the course of the illness in case 3. For explanation see text.

Fig 13—(Case 2) Photograph taken two weeks after the first intrathecal injection of PPD. The top of the plaster immobilising the left knee can be seen.

comparable. As in case 1 the temperature rose abruptly twenty four hours after the first injection, and twenty four hours later the C.S.F. became yellow and the protein shot up from 240 to 880 mg per 100 ml. The rise in cells was much less dramatic and was only from 60 to 140 per cmm on the fourth day. In this case the clinical disturbance was most alarming. Together with the rise in temperature he vomited persistently and complained that his neck and back were very painful and stiff and that he felt very ill. He then rapidly went into profound coma and for twelve hours looked as though he was going to die. However, during the next few days the coma lightened persistently, and twelve days after the injections he was better than he had been for weeks. He was able to sit up in bed and read the newspaper, he was no longer incontinent, and on two occasions the lumbar pressure was within normal limits (fig 13). However, during the third week his improvement flagged, the vomiting and intense drowsiness returned, and the C.S.F. pressure was once again persistently above 300 mm H₂O.

Seventeen days after the first two injections of PPD a third lumbar injection was given, but of only a tenth of the original dose—i.e., 0.075 µg PPD. Again there was a prompt clinical response which, though severe, was not as alarming as after the previous injections. The response in the C.S.F. was even more dramatic. The cells rose from 16 to 935 per cmm (80% polymorphonuclears) in forty eight hours and the protein to over 2 g per 100 ml. On the third day the fluid was brown and difficult to obtain, and spinal block seemed about to supervene. This immediate disturbance in the cells and protein settled down within forty eight hours, but the boy remained drowsy and incontinent, and after first falling the protein again rose.

Recovery

Twelve days after the injection the boy was no better, and accordingly it was decided to abandon all further intrathecal therapy. The day after this decision was taken he began to improve. The cells, protein, and pressure all fell persistently and permanently, the boy stopped vomiting and began to eat. The effusion in the knee disappeared leaving full movement of the joint, and radiography showed considerable improvement in the chest. During October he gained 12 lb, and from then on his improvement has been uninterrupted.

On Feb 6, 1950 he was transferred to Peppard Sanatorium, and at the end of March the intramuscular streptomycin was stopped. He is now (May 1950) free from all neurological signs and symptoms, and the C.S.F. is approaching normal. The lung lesion, however, is still active and an artificial pneumothorax has been induced. Mentally his recovery appears complete (fig 14).

Response to Tuberculin

By Aug 10, after three weeks of the second course of intrathecal injections, the outlook seemed so hopeless that it was seriously considered whether all injections should be withheld so that the boy might die in peace. Instead, 0.075 µg PPD—i.e., a tenth of the original dose given in case 1—was injected by lumbar puncture on both Aug 11 and 12. In this case the intrathecal streptomycin was continued so that all the readings of the C.S.F. should be

In this case, as in the first, intrathecal PPD produced a severe but temporary exacerbation of the meningeal symptoms which was quickly by a rise in the cell and protein content of the C.S.F. This disturbance in the C.S.F. resembled that so seen in the first weeks of intrathecal treatment with streptomycin, in particular the C.S.F. reaction. The third injection of PPD in case 2 was quite like that which coincided with the isolated film obtained at the end of the seventh week of treatment (fig 12).

More startling was the improvement seen in which was as gratifying as it was unexpected. Intrathecal injections of PPD, though possibly

Fig 14—(Case 2) Photograph taken fifteen months after treatment was first begun.

THIRD CASE (fig 15)

The patient, aged 5½, was admitted to the Maudsley Hospital for Head Injuries, Sept 18, 1949, with a 1½ weeks' history of drowsiness, anorexia, and vomiting. On admission she was semicomatose and unable to get up. Her neck was stiff, and there were constant athetoid movements of the right arm and she had a spastic left hemiparesis. The C.S.F. contained 212 cells per cmm (43% polymorphonuclears) with 122 mg protein, 30 mg sugar, and 772 mg ester per 100 ml. Radiography of the chest showed a calcified primary complex. Brain abscess was excluded by ventricular estimation and treatment with streptomycin was begun (50 mg daily by lumbar injection, 0.5 g twice daily by intramuscular injection). In spite of this the child rapidly worsened. She became profoundly comatose, incessant chewing and sucking. She was unable to cry, or swallow and had to be fed by stomach tube. The skin broke down over the pressure points, the stiffness of the neck and back progressed to severe opisthotonus, and the right arm assumed the tonic extensor posture. Shortly afterwards the left arm also became extended and hyperpronated and the decerebrate picture (of fig 1) was complete. Tubercle bacilli were identified in the C.S.F. on the fourteenth day of treatment.

Response to Tuberculin

On Oct 2, 1949, the fifteenth day of treatment, the intrathecal injections of streptomycin were temporarily withheld so as not to confuse the effects of the intrathecal PPD. Mantoux test at this time was weakly positive to 0.1 or 1/100,000. As the initial reactions in cases 1 and 2 had been so severe only 0.0075 µg PPD was introduced at first injections, and the dose was then gradually increased. All the injections caused an increase in the fever, and

1—Graph of the cells protein and temperature in a patient with meningitis. Mantoux test positive 0.1 ml. OT 1/1000. Intramuscular injections of increasing amounts of OT were given 1.4 ml. OT 1/10 was tolerated without disturbance and the Mantoux test was negative to 0.1 ml. OT 1/10. During a systemic infection the C.S.F. remained normal, but an intrathecal injection of 75 μg given after the Mantoux test had become negative still gave a brisk meningeal response (cf figs 7 and 8).

standard" solution of PPD is made up containing 7.5 μg/ml and this is further diluted 10 fold, 100 fold, and 1000 fold. If the Mantoux test is strongly positive, then 0.1 ml. of the 1000 fold dilution is injected intrathecally and amount is doubled every other day until a reaction is met.

If the Mantoux is weakly positive to OT 1/1000 or more 0.1 ml. of the 1000 fold dilution is injected and the dose is first trebled or even quadrupled every other day, depending on the strength of the Mantoux reaction. When we are using 0.5 ml. of the 100 fold dilution we increase the dose more gradually in order to avoid too severe a reaction. Once a reaction is obtained, as shown either clinically or by rise of the cells and protein in the C.S.F., the same dose is continued. From then on the size and timing of each injection is decided according to the severity of the last reaction. As a whole it has seemed wiser to give the injections every four or five days so as to allow two or three days free of fever and vomiting. The dose is gradually increased as the patient becomes more tolerant of the injections.

The reactions consist in an acute exacerbation of the meningeal signs and symptoms. At the worst they are extremely alarming and include profound coma, an increase in intracranial pressure requiring repeated lumbar taps, rhythmic respirations, hyperpyrexia, fits of tonic extensor rigidity. They have so far been mercifully short lived and about twenty four hours after the injection the patients have begun to improve.

We do not yet know how long the injections of tuberculin should be continued, but we have stopped only when the patients have become convalescent and are free from signs and symptoms of active meningitis.

The history of tuberculin teaches one of the sharpest lessons in medicine on the dangers of premature publication. We are only too well aware how incomplete this is. But now that tuberculous meningitis has been treated in such a long-drawn out disease it will be at least a year or eighteen months before the place of

tuberculin in treatment can be assessed. We are therefore putting forward this interim report in the hope that other workers in the same field will extend our observations.

SUMMARY

When tuberculous meningitis is treated for a long time with intramuscular and intrathecal streptomycin, between 50% and 60% of patients recover. But the mortality has not been further reduced and in the individual case the prognosis remains uncertain.

The fluctuations of the cells and protein in the C.S.F. during the first few weeks of streptomycin therapy suggests that tuberculin is liberated into the C.S.F.

In patients without meningitis but sensitized to tuberculin, as shown by a positive Mantoux test, an intrathecal injection of minute amounts of the purified protein derivative of tuberculin (PPD) produces fever and vomiting and also a pleocytosis and a rise in protein in the C.S.F. indistinguishable from the changes seen in untreated tuberculous meningitis. Rather larger doses reproduce the changes seen in cells and protein when tuberculous meningitis is treated with streptomycin. In patients in whom the Mantoux test is negative there is no clinical response and the disturbance of the C.S.F. is negligible.

C.S.F. collected during the first few weeks of streptomycin therapy and (after Seitz filtration) injected into the skin gives no reaction. The result of intradermal injections of C.S.F. collected and filtered twenty four hours after an intrathecal injection of PPD is also negative. Possible reasons for this are suggested.

In certain cases of tuberculous meningitis in which streptomycin has failed to effect a cure, the C.S.F. becomes sterile and the fluctuations in the cells and protein disappear. In two such cases the intrathecal injections of PPD, given when the patients were apparently moribund, reproduced the rise in cells and protein seen typically during the first few weeks of streptomycin therapy. In both patients these injections were followed by a totally unexpected recovery which appears to be complete over a year after treatment was first begun.

Intrathecal injections of PPD were given in a third case in which the full decerebrate state had developed. The illness was prolonged for six months and a definite objective improvement was seen though this never amounted to a useful recovery. At necropsy, no exudate was seen macroscopically surrounding the brain stem—a finding unprecedented in our experience. Microscopy showed several small foci of tuberculous granulation tissue in the cisterna interpeduncularis and one large focus lying beside the left optic nerve.

In all three cases severe exudate must have been present and have resolved after the PPD was given. It is therefore suggested that the effects of tuberculin should be further explored now that any consequent spread of infection can be controlled by giving streptomycin at the same time.

The necessity for giving PPD directly into the C.S.F. is briefly discussed.

Combined treatment with intrathecal PPD and streptomycin has been begun in seven other cases selected as having a bad prognosis. It is still too early to assess the results but there has been only one death in the first three months of treatment. This compares favourably with the results on streptomycin alone.

The dangers of intrathecal injections of tuberculin in the presence of active meningitis, and the precautions to be taken, are emphasised.

We would like to express our gratitude to those who have made this study possible and especially to Captain N. D.

Fig 17—(Case 3) Drawing of similar section to fig 16. The basal meninges are thickened but the cisterna ambiens is free from exudate.

DISCUSSION

In these 3 cases the effects of the intrathecal injections of P.P.D. on the cells and protein of the C.S.F. faithfully reflected the changes so commonly seen during the first weeks of treatment with streptomycin. Exactly similar changes could also be produced at will in subjects without meningitis but sensitised to tuberculo-protein, provided enough P.P.D. was given. With smaller amounts the changes in the C.S.F. were indistinguishable from those of untreated tuberculous meningitis.

Even more interesting, in all 3 cases an entirely unprecedented clinical improvement took place. The inference is inescapable that intense exudate had developed in all in spite of vigorous treatment with streptomycin, and that it had resolved after the P.P.D. was given.

How this resolution was brought about is a matter of conjecture. What these patients in fact received was tuberculin therapy given under a cover of streptomycin. Koch himself, when he first announced the discovery of tuberculin, said "There is no question of a destruction of the tubercle bacilli in the tissues, but only that the tissue enclosing the tubercle bacilli is affected by the remedy" and again "The remedy does not kill the tubercle bacilli but the tuberculous tissue" (Koch 1890).⁴ The hysterical enthusiasm provoked by Koch's paper was quickly followed by an almost equally hysterical rejection of the man and his "remedy". But in spite of the vast amount of careful work that followed the period of "tuberculin delirium" (Hamman and Wolman 1912) the therapeutic value of tuberculin could never be proved while its dangers were incontrovertible. Just two months after Koch's announcement Virchow (1891) demonstrated the post mortem findings in certain cases treated with tuberculin and showed intense and wide spread dissemination, and severe local extension of the disease. Now, however, we possess in streptomycin an antibiotic of proven efficacy against the tubercle bacillus. It should therefore be possible to explore and exploit the effects of tuberculin while preventing any spread of infection by giving streptomycin at the same time.

We are using intrathecal tuberculin as well as streptomycin in 7 other cases of tuberculous meningitis.⁵ These were specially selected as having a bad prognosis. 4 patients were deeply comatose and the other 3 drowsy

and severely confused. All had focal neurology. It is still too early to assess the results, but the pace we are gaining is encouraging. Only 1 has died during the first three months of treatment, whereas on streptomycin alone, in more than 100 fatal cases, the patients died within the first three months.

The falling response to intrathecal tuberculin in case 1 has been amply confirmed in some of the other cases. There is little doubt these patients have become desensitised (Rich and McCordock 1929, Child, Friedenwald, and Bernstein 1934, Rich 1934). At the same time there is some indication that the inflammatory reaction provoked by the tuberculin itself is beneficial, perhaps because it activates the defence process and brings streptomycin, or the natural and chemical defence mechanisms, into closer contact with the site of infection.

Whether or not it is necessary to give tuberculin directly into the C.S.F. is a question now being investigated in man and guinea-pigs.⁶ Preliminary results strongly suggest that intrathecal injections are not necessary. We have several times seen attacks of fever and after intramuscular injections of tuberculin in patients with normal meninges. Throughout these systemic reactions the C.S.F. has remained normal in all respects. On the other hand, and conversely, when repeated intramuscular injections were given until large amounts of tuberculin were tolerated without any disturbance whatsoever, and the Mantoux test had become negative to 0.1 ml or 1/10, an intrathecal injection of P.P.D. still provoked a dramatic rise in cells and protein (fig 19).

One thing, however, is very certain. Intrathecal injections of P.P.D. in the presence of active meningitis are potentially extremely dangerous. Further, the severity of the reaction is to some extent unpredictable, especially if for any reason the P.P.D. has been withheld for a few weeks. The closest supervision of cases and daily analysis of the C.S.F. are essential if disaster is to be avoided. We are at present using the following schedule of treatment in an attempt to produce a tuberculous reaction as quickly and as safely as possible.

On admission 0.1 ml or 1/1000 is injected intradermally. Then, as soon as the diagnosis is confirmed, bifrontal burr holes are made if this has not already been done.

⁶ Systemic tuberculin has been tried in tuberculous meningitis also by Don (1907) and Hamman and Wolman (1912), and by streptomycin by Choremlis et al (1948).

Fig 18—(Case 3) Section of brain made just above the section fig 17. The Sylvian fissures are free from exudate. An old infarct can be seen in the right basal ganglia and just below it a small tuberculoma in intimate contact with the Sylvian fissure.

⁴ Nun so viel steht fest dass es sich nicht um eine Abtötung der im Gewebe befindlichen Tuberkelbacillen handelt sondern dass nun das Gewebe welches die Tuberkelbacillen einschliesst, von der Wirkung des Mittels getroffen wird. Das Mittel tötet also um es noch einmal kurz zu wiederholen nicht die Tuberkelbacillen sondern das tuberkulöse Gewebe.

⁵ A single intrathecal injection was also given in an 8th case immediately after the diagnosis had been confirmed bacteriologically. The patient who had only been in hospital twenty-four hours died a few hours later from an inhalation bronchopneumonia that was present on admission. This case is excluded from this discussion because no information was gained about the action of intrathecal tuberculin.

d, for the first time a suitable sedative regime epilepsy

5—Mr E, Eurasian, aged 19, had had leprosy ever since he could remember. Many bacilli were present.

Treatment with thiocetazone started on April 5, with two tablets daily and increasing to six daily, in divided doses.

Remarks—Bacilli are still present but in every stage of degeneration. Along with this there has been a very definite improvement. At the start of treatment the patient had a very granulosomatous thickening on the face, trunk, and limbs. This thickening has become flatter and the skin is now more normal in appearance.

We can only consider an advanced case of this type in the initial stages of treatment. However, after four months' treatment has led to a considerable clinical improvement and bacillary degeneration.

Case 6—Mr F, Eurasian, aged 40, had been treated from 1937 until April with a proprietary sulphone. He was a severe tuberculoid case and had been bacteriologically negative from the beginning. His treatment with sulphones followed by a very pronounced deterioration in his condition. He developed acute tuberculoid leprosy, with considerable depression and low fever. He was next treated with injections of hydnocarpus oil which appeared to have a beneficial effect on his condition. In the middle of April it was decided to start treatment with thiocetazone. Since then the patient has improved with considerable rapidity. After three months' treatment the lesions are hardly visible, his depression has gone.

It can easily be argued that this case proves the value of acute tuberculoid leprosy in many cases a latent state from which the patient may possibly recover without any treatment whatever. But in the present case the flare up was a severe one, aggravated by sulphone treatment, and showed no improvement even after large doses of hydnocarpus oil. There is little doubt in my mind that the prompt clinical response is due to treatment with thiocetazone. In this case the dose was never more than four tablets a day.

Case 7—Mr G, aged 48, had developed leprosy in a Chinese prison camp where no treatment was available. He was an advanced lepromatous case and had been given quite adequate sulphone treatment for three years. This treatment had no effect on the number of bacilli present in his smears. Any attempt to raise the dose of sulphone beyond many limits had led to extreme nerve pain. The patient had been extremely depressed and had recently felt that his treatment was not doing him any good.

Treatment—On April 5 sulphone treatment was suspended, the patient was given thiocetazone starting with two tablets daily and going on to four daily in divided doses. There has been some clinical improvement but not much. The number of bacilli has definitely decreased, and the nerve pain has disappeared.

This is one of those very difficult and highly resistant cases which do occur under sulphone treatment but are uncommonly recorded. In the last three years the patient has had different proprietary sulphones and a long term of treatment with *p*-aminosalicylic acid. The drug which seems to have produced any clinical benefit is thiocetazone.

Case 8—Mr H, aged 40, had had virulent and advanced lepromatous leprosy for at least twelve years. A lepromin test was negative and the patient when first seen at the beginning of March, was suffering from violent lepra fever with a temperature of 103°F and extreme depression. He was given two tablets of thiocetazone daily, and the dosage since then increased to five tablets daily. He is still bacteriologically positive, but the lepra fever has disappeared and the change in his clinical and psychological condition is considerable.

Case 9—Mr I, Eurasian, aged 19, was first seen over a year ago. He had had virulent leprosy for more than ten years. After a year's treatment with sulphone he had improved very considerably and showed scanty bacilli, but

his lesions were still obvious. At the beginning of May, 1950, treatment with thiocetazone (four tablets daily) was begun. The result has been rapid and dramatic. The patient said:

"I don't seem to be able to recognise myself on looking in the mirror. I do find the markings on my face going away completely." The last bacteriological smears showed no bacilli.

Case 10—Mr J, aged 20, who had come to this country from West Africa, had lepromatous leprosy, with lesions on the face and chin. He had had no previous treatment of any kind. He was treated with thiocetazone for three months, the dosage starting at two tablets daily and increasing to six daily. The clinical improvement has been quite remarkable. The patient has become bacteriologically negative, and there is no clinical evidence of leprosy, the granulomata having completely disappeared.

COMMENTS

A study of the effects of any drug on leprosy after only four months' treatment is utterly inadequate for any real assessment of its value. It will be noted, too, that the present cases were all of an advanced and virulent type, many having undergone years of misdiagnosis, improper treatment, and neglect. I am, however, prompted to publish this preliminary report because of the initial success with thiocetazone, and in the hope that others who have more clinical material may be led to test this remedy. None of the present patients could expect a clean bacteriological and clinical bill of health under a minimum of two years' treatment with sulphone.

Thiocetazone seems to have three advantages:

(1) Under sulphone treatment clinical improvement in advanced leprosy does not normally occur in under a year, and bacteriological improvement comes even later. In each of the present cases with one possible exception (case 4), there seems to have been definite clinical amelioration and some bacteriological improvement within four months of the start of treatment. This is not a period in which any analogous effects would be expected from sulphone treatment.

(2) Published reports of the sulphone treatment of leprosy have hitherto neglected to mention the mental depression and slowing of cerebration which so often attend its administration. Indeed they are not always obvious except where the patient is doing intellectual work. Thiocetazone seems to be completely free from this handicap and the difference in the mental demeanour of patients who have been given thiocetazone after having been previously treated with sulphones is striking.

(3) So far as can be ascertained in the present small series thiocetazone, in the doses recommended here, seems to be relatively free from toxicity. There has been no evidence of anaemia or of hemolysis, and no tendency to lepra fever, which is a very present danger with sulphone treatment. It is usually considered necessary that patients under sulphone treatment should have their blood examined at least once a month, but in my small series this was unnecessary with thiocetazone.

CONCLUSION

It is obviously far too soon to make anything more than a tentative assessment of the early effects of treatment. But the clinical and bacteriological effects of thiocetazone, as recorded above, and its apparent lack of toxicity, suggest that it is well worth fuller study.

I am deeply indebted to Dr W. A. R. Thomson for a considerable number of discussions about dosage and general treatment with thiocetazone, and to the Royal Free Hospital, London, for the laboratory investigations. Messrs Boots Pure Drug Company supplied the thiocetazone.

THIOSEMICARBAZONE IN THE TREATMENT OF LEPROSY

GORDON A RYRIE

M.A., M B Edin

MEDICAL SECRETARY, BRITISH EMPIRE LEPROSY RELIEF ASSOCIATION

SINCE *Mycobacterium lepræ* cannot be cultivated either in vitro or in vivo, research on the treatment of leprosy often follows along lines that prove hopeful in tuberculosis. Certain of the thiosemicarbazones seem to exert, in certain circumstances, a specific effect on *Myco tuberculosis*, including changes in the morphology and staining power of the bacillus, an action on the toxins of tuberculosis, and regressive changes in tuberculous lesions (*Lancet* 1950)

In the early part of this year I was approached by Sir Jack Drummond, F R S, and Dr W A R Thomson, of the research and medical departments of Boots Pure Drug Company, with the suggestion that it might be of value to investigate the effect of the thiosemicarbazones in leprosy

The present study is of the exlubition of 'Thiacetazone' (p acetylaminobenzaldehyde thiosemicarbazone) in ten cases of leprosy in Britain. Eight of these cases were of a virulent lepromatous type, two of them were of the chronic tuberculoid type. In all cases the dosage started at 50 mg of thiacetazone, and this has been raised over a matter of 4-8 weeks to 150 mg daily. Since thiacetazone is made up in tablets each containing 25 mg of the drug, the preliminary dose is represented by two tablets, the biggest dose being six tablets. The latter doses have all been given at divided periods throughout the day

CASE RECORDS

Case 1—Mrs A. aged 44, had had lepromatous leprosy for six years, the disease having first appeared as lepromatous lesions on the forehead, face, thighs, and legs, which were all thickened, raised, and yielded leprosy bacilli. A lepromin test was negative. In my estimation, under expert sulphone treatment she would have required a minimum of 2½ years' treatment before she became clinically and bacteriologically negative

Treatment with thiacetazone was started in the second week of March, beginning with two tablets a day and increasing by one tablet a week to six tablets. On six tablets the patient said that she felt some gastric uneasiness, so the dose was reduced to five tablets, and she has made no complaint since

Result—Improvement was rapid. After four weeks' treatment the patient became bacteriologically negative, and she

has remained so (six examinations). The lesions of and forehead have completely flattened. The thighs and legs are still visible but have much paler and flush with the surface of the skin. Two months the patient found that she could wear ring for the first time for a year. She has shown a increase in physical energy. She has been given treatment

Since the lepromin test was negative, this is one in which there was little or no specific the disease

Case 2—Mr B, Cypriot, aged 31, had had leprosy for at least twelve years. Huge indurated disfigured the whole of his face. Eighteen months had been treated experimentally with p-aminosalicylic acid. After four months of this treatment he became restive, complaining that the drug was doing him. He became morose and melancholy and threatened p-aminosalicylic acid was then stopped, and the treated for a year with a proprietary sulphone. Full of sulphone were reached fairly rapidly, and slight but improvement resulted, but there was little change. A lepromin test was negative

Treatment—On April 7 treatment with thiacetazone begun, starting with two tablets daily, the dose was increased to six tablets daily

Result—*Myco lepræ* are now very scanty, but appearance remains unaltered. The lesions have very noticeably receded, the nodules of the face in particular soft and umbilicated

It cannot be held that the result in this case is a psychological effect of a new treatment. The has had from the very beginning complete confidence in his doctor, and before starting sulphone treatment had already read accounts in the lay press about "wonder drug". It might be held that his improvement may be merely a continuation of a process initiated by the previous use of sulphones, but this is unlikely, for sulphones are fairly rapidly eliminated from the system. I have seen cases in which there been partial or inadequate treatment with sulphone and none of these cases has ever shown any clinical improvement. This patient has had no other drug, the change in his condition can only be attributed the effects of thiacetazone

Case 3—Mrs C, aged 37, had had leprosy for more than ten years, with long continued lepra fever and bacteriologically positive lesions. On examination she was found to be emaciated and had ulcers on her trunk and forehead and hyperpigmented patches all over the upper trunk. She had been treated for about six months with a proprietary sulphone, but had got to the stage when even a single maximum dose caused a violent upsurge of lepra reaction, fever and confining her to bed

Treatment—On April 7 treatment began with a tablet of thiacetazone. This dose was very gradually cautiously increased to four tablets daily

Result—The patient has clinically improved very considerably indeed. The bacilli are very much less and the patient can get about and do a day's work. She still has occasional transient reaction nodules, but her general condition and appearance have much improved

This case is extremely difficult to assess. The patient could not tolerate sulphone, and her pregnancy and the probability of a steady deterioration in her leprosy condition

Case 4—Mr D, Eurasian, aged 19, had had leprosy as long as he could remember. He also had epilepsy, attacks about twice a week.

Treatment with thiacetazone began on April 4, but patient refuses to take the drug when he thinks an attack of epilepsy may be imminent, and it is hard to be much he has had

Result—There is definite evidence of clinical improvement and the patient looks and feels very much better. *lepræ* are still present

Little or nothing can be claimed in a case like especially as, along with the thiacetazone, the

less of the right kidney, and infarction was suspected. The urine was alkaline, contained much albumin, many red cells, and numerous epithelial cells; culture was negative.

Albumin and red cells were subsequently found on Oct 19, and on Oct 20. A blood count showed Hb 13.5 g per 100 ml, red cells 4,100,000 per c.mm., leucocytes 11,650 per c.mm. (polymorphs 77%, lymphocytes 21%, monocytes 2%). The diastolic pressure had fallen considerably, the pulse being 130/100.

Treatment—In view of the patient's serious condition a course of penicillin 250,000 units three hourly was begun on Oct 19, and to 500,000 units three hourly on Oct 20, and to 1 mega unit three hourly on Oct 21.

Penicillin was then withdrawn, a pint of blood was given, and a course of streptomycin 1 g t.d.s. was begun on Oct 22 because of the persistent pyrexia and until Nov 19, when the dosage was reduced to 0.5 g. Streptomycin was withdrawn on Nov 24.

Recovery—The patient had clinically improved on the day after the start of streptomycin therapy. The petechiae on the chest and abdomen faded rapidly, and no more were subsequently seen. On Oct 26 the diastolic pressure had risen to 25 mm Hg. The cardiac murmurs were not materially changed. Subsequent progress was uneventful. On Nov 7 the urine contained albumin 40 mg per 100 ml, and on Nov 14 the patient was discharged. There has been no recurrence of fever up to now.

Case 3 (fig 3)—A girl factory worker aged 20, was treated under the care of Dr D. G. L. Brwaters on Feb 15,

Fig 3—Temperature and treatment chart of case 3

with pyrexia and sweating, she had not responded to late therapy at home and had been febrile for about a week. She had had rheumatic fever at the age of 7 years and intermittent joint pains ever since, in view of her cardiac history she had attended a school for physically defective children.

Admission—On admission she was sweating and had a rapid and bounding pulse, there were rough systolic and diastolic murmurs at the apex, an aortic systolic murmur, and a holosystolic murmur to the left of the sternum. The blood pressure was 150/80 mm Hg. The spleen was not palpable. The skin was free from rashes. There was no clubbing of the fingers. The urine contained albumin 10 mg per 100 ml, red cells, and numerous epithelial cells, but no pus or casts. A blood count showed Hb 10.2 g per 100 ml, red cells 4,000,000 per c.mm., and leucocytes 13,200 per c.mm. (polymorphs 63%, lymphocytes 31%). Blood cultures were negative on Feb 19, 22 (two), 23 (two), 24, 25, April 16, 17, and 19 and May 5 and 25.

Course—For 2½ weeks there was intermittent fever up to 102°F daily.

On Feb 22 the patient was seen by Dr Paul Wood, who despite negative blood-culture and absence of embolic phenomena, that the evidence for a presumptive diagnosis of subacute bacterial endocarditis was strong enough to start penicillin therapy. A few petechiae were seen on the trunk on Feb 25 and 26, and the urine contained numerous red cells, epithelial cells and some leucocytes.

Treatment—The fever was controlled for three weeks with penicillin 4 mega units daily. The fever then recurred and on Feb 11 penicillin was withdrawn to reinvestigate the blood cultures. After this the fever remained uncontrolled

with large doses of penicillin—i.e., 4, 8, and 12 mega units daily, and with sulphadimidine. Streptomycin 2 g daily was then given with dramatic results. Treatment was continued for about four weeks until June 24, when toxic symptoms put an end to it. After the start of streptomycin therapy the general condition much improved and the fever permanently subsided, although fresh petechiae still appeared as late as June 11. The dramatic improvement in weight, haemoglobin, and E.S.R. following the exhibition of streptomycin were as follows:

Date	Weight (kg)	E.S.R. (mm in 1 hr)	Hb (g per 100 ml)
May 13	49.6	—	—
May 20	—	122	9.6
May 21	50.0	—	—
May 26	Streptomycin therapy begun		
May 27	51.2	126	—
June 2	—	90	—
June 4	52.5	—	—
June 25	53.5	Streptomycin stopped	
June 30	—	—	11.3
July 30	—	15	—
July 31	56.9	—	—
Aug 12	—	—	15.2

The patient's convalescence was uneventful except for an attack of paroxysmal auricular fibrillation on June 25. On Nov 24 she was re-examined and found fit to start light office work.

DIAGNOSIS

Since chemotherapy provides fresh hope of cure for these cases, it is clear that early diagnosis is essential. A few years ago there was no urgency of diagnosis, which was often delayed until the clinical picture was full-blown and blood culture positive. Nowadays such an attitude is unjustifiable. Blood culture is a very crude test, and in many cases the patients are gravely ill in spite of negative bacteriological findings and urgent treatment is imperative to save life. For this purpose it is important to institute treatment at the earliest possible moment. Subacute bacterial endocarditis should be strongly suspected in any case of protracted fever in patients with valvular disease of the heart and no other obvious infection. Where there is evidence of embolic phenomena in skin, urine, or spleen, the diagnosis should be made in the absence of bacteriological proof, and treatment instituted where the severity of the illness demands it. In these cases

large doses of penicillin—e.g., 2 mega units daily—are at first advisable. Should the fever remain uncontrolled, further blood-cultures should be made in the hope of isolating the organisms and investigating their penicillin sensitivity. If they are penicillin resistant the dosage will have to be increased. If the fever still remains uncontrolled and the patient is severely ill, streptomycin is worthy of trial.

STREPTOMYCIN TREATMENT

Success with streptomycin in this disease was first recorded in 1946, and since then about 50 cases have been successfully treated with it, though it should be remembered that many of these cases were also treated with penicillin and sulphonamides. Study of the American reports shows that in about 22 cases streptomycin was mainly responsible for cure on clinical grounds, but only 8 of them were treated with streptomycin alone (Wallach and Pomerantz 1949). The organism isolated by blood-culture in 4 of these was *Strep. viridans* and in 2 cases *Haemophilus influenzae*.

The dosage and duration of treatment in this condition cannot be assessed in the present state of knowledge, it is clear that toxicity with streptomycin is more likely with larger dosage over a long period. For this reason it would seem wiser to find the smallest effective dose to control the fever as judged by a four hourly temperature chart. The necessary duration of treatment is probably about three or four weeks.

STREPTOMYCIN IN SUBACUTE BACTERIAL ENDOCARDITIS

REPORT OF THREE CASES

PHILIP H WILLCOX

M D Camb, M R C P

PHYSICIAN (CANADIAN RED CROSS MEMORIAL HOSPITAL,
TAPLOW ASSISTANT PHYSICIAN, KING EDWARD VII
HOSPITAL, WINDSOR

Penicillin treatment has proved so successful in subacute bacterial endocarditis that a high probability of cure may be entertained in cases diagnosed early, but success, which can in no case be guaranteed, depends on early treatment, on sufficiently large and prolonged dosage, and on the penicillin sensitivity of the organism (Christie 1948, 1949)

Some cases not only fail to respond but become worse in spite of such treatment, and may yet be saved by the use of streptomycin. The following three cases of rheumatic carditis, with mitral and aortic valvular disease in each case, all illustrate the success of streptomycin after the failure of penicillin in large dosage to overcome the infection. Cases 1 and 2 were under my care, and case 3 was under the care of Dr E G L Bywaters (to whom grateful acknowledgment is made for the use of the notes) in the special unit for rheumatism at the Canadian Red Cross Memorial Hospital

CASE RECORDS

Case 1 (fig 1)—A man, aged 29, was admitted on May 31, 1949, with six days' history of headache, sweating, and aching pains in the arms and legs. His right eye was bloodshot. He

Fig 1—Temperature and treatment chart of case 1

had vomited once only. He had had rheumatic fever in 1938, and during convalescence evidence of rheumatic carditis affecting the mitral and aortic valves had been found.

On examination he was febrile and looked toxic and pale, there was a subconjunctival haemorrhage in the right eyelid. There were no joint swellings or rash. The pulse was regular and collapsing. The apex beat was in the fifth interspace 8 cm from the midline. There were a rough systolic murmur at the apex and systolic and diastolic aortic murmurs, the latter conducted down the left side of the sternum. Blood pressure 120/85 mm Hg. The spleen was not palpable and not tender. The lungs showed no abnormal signs. There was a trace of albumin in the urine, but no red cells or casts in the deposit.

Progress—Six blood cultures in his first three days in hospital grew no pathogenic organisms. On the fourth day the spleen was definitely easily palpable. On this day (June 3) the haemoglobin was 13.1 g per 100 ml, white cells 16,600 per c mm (polymorphs 84%, lymphocytes 9%, monocytes 5%, plasma cells 2%). The erythrocyte sedimentation rate (E.S.R.) was 64 mm in one hour (Wintrobe), and packed cell volume 35 c cm per 100 ml.

Treatment—Subacute bacterial endocarditis was and, owing to the man's serious condition, a penicillin 150,000 units four hourly was begun. It did not control the fever, the dosage was increased to units four hourly on June 4, 500,000 units, on June 9, 1,000,000 units four hourly on June 11, 14 units four hourly on June 18.

Progress—The fever remained uncontrolled. On the man's spleen was two finger breadths enlarged, were presystolic and mid diastolic murmurs at the faint macular rash at the back of the chest which extent next day was thought to be due to penicillin. A purplish node was seen on the dorsum of the right June 12. There was a slight rigor, and an maculous rash, urticarial in places, was seen on the trunk. A small area of redness and tenderness on of the right foot was thought to be embolic. A swelling was seen on the left fourth toe. Tender on the left index finger on June 16 and 21, on the second finger of the right hand on June 18, and on right palm on June 20. A fresh embolic spot the right hand on July 2. On July 4 albumin, cells and pus cells, but no casts, were found in the urine.

Streptomycin—On June 13 Dr Paul Wood advised mycin in view of the unsatisfactory response to large dosage. A course of intramuscular streptomycin bd was begun on June 14. This had at first little effect on the fever in spite of the concurrent tion of penicillin, but after the dose had been increased 1.5 g bd on June 21 the fever was controlled. The was increased to 2 g bd on June 30, and reduced to 1.5 g bd on July 5, and to 0.5 g daily on July 29. Streptomycin was withdrawn on July 31. 1 pint of blood was on June 22 and another on July 2 without causing reaction.

Streptomycin toxicity was noticed on July 2 consisting giddiness, occipital headache, and difficulty in focusing. Ataxia, especially at night, and slight giddiness have been noticeable ever since, and were still complained of on Jan. 1950, though there had been no recurrence of fever, and the patient had resumed his occupation as a carpenter and was feeling fit.

Case 2 (fig 2)—A young man, aged 23, had of backache and fever for seven days before admission of irregular pyrexia between 99° and 101°F. He had several known attacks of rheumatic fever at the ages 7 years, 13, and 20.

On admission on Oct 14, 1949, he was pale, with a tongue. His pulse was collapsing but regular. There evidence of gross clinical enlargement of the heart, the apex beat being in the anterior axillary line and the impulse. The first sound was loud at the apex, and there were systolic and diastolic murmurs. There was a rough systolic at the base and a well marked diastolic murmur down the left side of the sternum. His blood pressure 140/30 mm Hg. No abnormal signs were found in the liver and spleen were not palpable. The teeth and were healthy. No petechiae or other embolic phenomena apparent. Three blood cultures on Oct 15 and 16 grew organisms. Subacute bacterial endocarditis was in the absence of any other cause of his pyrexia.

Progress—On Oct 16 the patient began to complain of central abdominal pain, and this persisted until Oct 18 it was felt in the right renal region. A few petechiae visible on the chest and abdomen. There was well marked

Fig 2—Temperature and treatment chart of case 2

thrombus in the veins but no signs of intimal or base of the arteries

DISCUSSION

case illustrates the characteristic features of il gangrene secondary to venous thrombosis as by the triad of Andrieu and Haimovici (1938) il gangrene was due to arterial spasm seems to be proved by the fact that the femoral artery is in a state of spasm when exposed at operation but vigorous pulsation after ligation and division seems to prove also that spasm is the cause of gangrene in these cases, and not widespread venous thrombosis as postulated by Haimovici and Suffness.

great interest is the associated pulmonary embolism, which is noted fairly commonly in the literature (e.g. 1938, Koch 1940, McNailev 1932). The postoperative emboli were associated with slight oedema of the leg, from which they probably originated. (1949) states that if pulmonary embolism occurs in a patient with phlegmasia alba dolens it can be deduced that the emboli have originated in the unswollen leg and this is borne out by the sequence of events in this case.

The possibility of organic arterial disease can be deduced from the operation findings and the dissected iliac artery. Paradoxical embolism is a remote but unlikely possibility. Theoretically after pulmonary embolism the increased pulmonary arterial pressure enhances the likelihood of paradoxical embolism, but the femoral pulsation after division seems to exclude this. The iliac embolus lodged peripherally may have caused arterial spasm, but could not be found on dissection. It would seem that cases of phlegmasia alba dolens can be treated energetically on the lines laid down by Hensler (1947)—i.e., by early paravertebral sympathectomy. The newer antispasmodic drugs—e.g., the guanethidine compounds—may prove of value in the treatment of the definite risk of gangrene if these measures are not effective. Lumbar sympathectomy is indicated in cases where it does not respond to these measures, particularly if the triad of Andrieu and Haimovici's triad is present. Anticoagulant therapy should be instituted early in these cases because so many are associated with pulmonary embolism, which in the present case preceded the gangrene by weeks.

SUMMARY AND CONCLUSIONS

Case of puerperal gangrene due to arterial spasm secondary to thrombophlebitis is described. This is probably now the commonest cause of puerperal gangrene and ergotism now play a minor role.

Phlegmasia alba dolens should be energetically treated, as it not only has a morbidity (i.e., chronic oedema of the affected leg) but also a local mortality (i.e., gangrene).

The association of pulmonary embolism with this type of gangrene is noted.

The author wishes to thank Mr J T Rice Edwards for permission to read and publish this case, and Dr T J Thomas for the surgical follow up.

New Inventions

EXCHANGE TRANSFUSION APPARATUS

EXCHANGE transfusion in infants with erythroblastosis foetalis is often complicated by faults or inadequacies in the apparatus. The Medical Research Council¹ suggested, for exchange transfusion, apparatus consisting of a 20 ml syringe to which are attached two stopcocks with side valves, the distal one of which is connected to the infant's vein via a 19-gauge needle inserted into the lumen of a plastic catheter.

Such apparatus has numerous disadvantages.

(1) Manipulation of an ordinary syringe becomes very tiring to the hands after numerous injections and withdrawals.

(2) Between the barrel of the syringe and the infant there are no less than three joints in line, all of which merely rely on being pushed together with a 'Record' or Luer fitting. At any or all of these joints air can be, and often is, sucked into the circuit. Moreover, as the operator tires he tends to become more clumsy in his movements and may easily detach a joint.

(3) The 'bottle neck' of the whole system is the lumen of the needle inserted into the 'Polythene' tubing, and this narrow diameter increases considerably the difficulties of exchange transfusion. It is also in the lumen

of the needle that the blood often clots.

(4) If at any time it becomes necessary to rinse the apparatus in an anticoagulant solution, it must be taken to pieces, rinsed and put together again with the inevitable introduction of air, and the risk of contamination by infection.

The apparatus illustrated here has been designed in an attempt to overcome these difficulties. It resembles that described by Farquhar and Lewis,² but with some differences. It consists of a syringe of 10 or 20 ml capacity equipped with three finger rings to give one-handed control and less tiring operation. The nozzle is adapted to carry a three-way tap which may be firmly screwed on to the syringe to make a rigid airtight joint. The three positions of the tap are clearly indicated by a pointer.

(1) Corresponding to the first position of the pointer is a female record fitting mount to which may be attached the male record tubing connector of the standard Blood Transfusion Service giving set. Blood can therefore be introduced into the syringe via the giving set from a bottle suspended by the side of the infant's cot.

(2) The central position is equipped with a screwed nozzle on to which is attached a cylinder containing a rubber bush. The polythene tubing is threaded through the cylinder and bush, and the tip of the tubing is then introduced into the screwed nozzle. The cylinder is screwed on to the nozzle and by compression of the rubber bush the outside of the tubing is firmly gripped. In this way the lumen of the tubing is not reduced and there is no smaller bore through which blood has to pass than that of the tubing itself. I believe Dr L. K. Diamond, of Boston, Massachusetts, was the first person to suggest that polythene tubing should be gripped in this fashion.

(3) The third position is occupied by a side branch stopcock giving two routes: one for the ejection of aspirated blood, the other for drawing anticoagulant solution into the syringe.

CONCLUSIONS AND SUMMARY

There is evidence that streptomycin is an effective weapon in subacute bacterial endocarditis and deserves further trial in cases due to penicillin insensitive organisms and in those in which there are troublesome reactions to penicillin.

Three cases with aortic and mitral valvular disease, treated successfully with streptomycin after penicillin in liberal doses had proved ineffective, are reported here.

Clinically the diagnosis was not in doubt, in spite of the failure to grow the organisms by blood culture.

Grateful acknowledgment is made to Dr E. G. L. Bywaters for the loan of the records of case 3, to Dr Paul Wood for his helpful advice in case 1, to Dr Michael Starks and Dr R. F. Brooks for their work and accurate records of cases 1 and 2, and to the nurses and pathology department of the Canadian Red Cross Memorial Hospital.

PUERPERAL GANGRENE

ALLAN CLAIN

L. L. NUSSBAUM

M.B. Cape Town, F.R.C.S.

M.B. Cape Town, M.R.C.P.

RESIDENT SURGICAL OFFICER

HOUSE PHYSICIAN

PONTYPOOL AND DISTRICT GENERAL HOSPITAL

Gangrene associated with childbirth is a long established albeit rare clinical entity. McNalley (1932) found that about 85 of 100 published cases were puerperal, 10 were post-abortal, and 5 occurred during pregnancy. In further reviews of the literature Benson (1937) and Tilley (1938) attributed most cases to septic thrombosis of the pelvic vessels in puerperal sepsis, combined often with the use of ergot. Benson noted that quite a number of cases affected the upper extremity and in McNalley's review 15% of cases fell into this category.

Benson, however, also noted that the gangrene was sometimes of venous origin, and Audier and Haimovici (1938), in an excellent review of gangrene of venous origin, attribute wet gangrene in puerperal cases to venous occlusion, and dry gangrene to arterial occlusion. They point out that the gangrene associated with thrombophlebitis may simulate arterial embolism, and they describe a triad found in these cases of venous gangrene—i.e., very severe pain in the affected limb, rapidly developing cyanosis (phlegmasia cerulea dolens), and oedema.

Experimentally Audier and Haimovici found it difficult to produce gangrene by venous ligation. Only, if the whole venous circulation is obstructed does gangrene develop. DeBailey et al. (1939) showed experimentally that simple ligation of a vein caused a decrease in the oscillographic excursion of the accompanying artery. If a segment of vein was isolated between ligatures and injected with a sclerosant solution, the oscillographic excursion was decreased much more, but a sympathetic block or sympathectomy relieved this spasm. This seems to be the cause of the type of puerperal gangrene of venous origin recently being increasingly reported (Gutman 1938, Koch 1940).

The cause of puerperal gangrene may thus be (1) arterial embolism, (2) arterial thrombosis, (3) arterial spasm secondary to thrombophlebitis, (4) venous thrombosis alone, or (5) a combination of these.

Arterial embolism is a theoretical possibility requiring a focus of origin for the embolus on the arterial side of the circulation, with pregnancy as a coincidental condition—e.g., bacterial endocarditis. The other possibility is that of paradoxical embolism.

Arterial thrombosis is the mechanism in cases associated with puerperal sepsis. Benson (1937) attributed this to arterial occlusion of the lower limb by a septic

thrombus originating in the pelvic vessels, but in this type of case was associated with the use of—i.e., there was an element of spasm—and the decreased incidence of severe puerperal sepsis possible with chemotherapy this condition is not to be seen.

Arterial spasm secondary to thrombophlebitis probably the cause in most cases at present. If so, the appearance of Audier and Haimovici's should be the signal for energetic antispasmodic therapy. Haimovici and Suffness (1948), in a discussion of gangrene of venous origin, consider, however, that arterial spasm plays a minor rôle in the causation of the widespread venous thrombosis present in the venous return, and there is thus a state of stasis with consequent tissue anoxia leading to gangrene.

CASE RECORD

Mrs. A., aged 39, was admitted to Pontypool and General Hospital on July 25, 1949, having been referred by her private doctor as a case of phlegmasia alba dolens.

On admission she was apparently in extremis, was cyanosed and shocked, with a blood pressure of 70/40. Pulmonary embolism was diagnosed, and resuscitative measures were adopted. Nikethamide was given, and a venous plasma drip was set up immediately, and the patient's blood was grouped and cross matched. Six pints of Rh positive blood was given during the next forty-eight hours. After a few hours the patient's general condition improved sufficiently to enable a proper history to be taken and thorough physical examination to be made.

History.—Nine weeks before admission the patient had been delivered of a normal child after labour had been induced for "swelling of the ankles." The puerperium had been uneventful until the third week, when she had developed pain in the right side of the chest, which had been diagnosed as pleurisy, and an effusion had been aspirated by her private doctor on two occasions. Two days before admission the patient had had severe "cramps" in the right leg, which had immediately become dark blue and enormously swollen. Previously, during the fourth month of the pregnancy, the patient had had in this leg a temporary swelling which had been diagnosed as phlebitis. She had had varicose veins in both legs for twelve years with no referable symptoms and had previously borne a normal child in 1939.

On examination the right lower limb was enormously swollen with pitting oedema and deeply cyanosed. Peripheral pulses were palpable, and the limb was cold, anaesthetic, and parietic. There was a suggestion of a line of demarcation about 2 in. below the knee. The thigh contained fluid at the right base, and a pleural fracture was heard at the left base.

Treatment.—At this stage the patient was heparinized. During the following day her general condition improved but a definite line of demarcation developed below the knee and the skin began to blister, so it was decided to amputate the limb.

Operation.—Under thiopentone, gas, oxygen, and intravenous ethylene anaesthesia (Dr H. Lister Wilson) the limb was amputated at the site of election in the thigh. During the operation the femoral artery was pulseless, but as soon as it was ligated and divided the proximal end began to pulsate vigorously. The tissues poured out oedema fluid during the operation.

Postoperative Course.—The patient improved gradually but on the third day she developed signs of a small pulmonary embolus in the left lung in spite of heparinization. This was probably originated from the left leg, which had been swelled and was crêpe bandaged. On the tenth day there was a further small embolus. These were confirmed radiologically. Heparin and penicillin were administered for two postoperatively, and the temperature settled gradually. Further postoperative course was uneventful, and the patient healed by primary intention. Radiography of the chest on Oct. 5 showed slight residual opacities and no fluid.

Pathology.—Dissection of the operation specimen showed widespread venous thrombosis involving superficial (the short saphenous vein) and deep veins, but the veins were all quite empty of blood. Gangrenous changes were present in the tissues below the line of demarcation. Logical examination of veins and arteries (Dr J. Fine) revealed

THE LANCET

LONDON SATURDAY AUGUST 19, 1950

The New Princess

Princess ELIZABETH, the Heiress Presumptive, gave birth to a daughter at Clarence House, her London home on Aug. 15. The first bulletin, signed by William Gillhott and Mr. John Peel (obstetricians), Dr. F. Hall (anaesthetist), and Sir John Weir (physician to the King), was issued soon after midday and read as follows:

"Her Royal Highness the Princess Elizabeth, Duchess of Edinburgh, was safely delivered of a Princess at 11.50 A.M. Her Royal Highness and her daughter are both well."

With the infant Princess weighed 6 lb 10 oz. The nation, having affectionately insisted on sharing the joy before her birth, will be quick to welcome the new Princess and wish her luck in a troubled world. Her Parents and Grandparents then offer their congratulations.

Treatment of Myasthenia Gravis

MYASTHENIA gravis cannot yet be called curable, but the outlook has certainly brightened since a few years ago, when BRAMWELL¹ could not see himself "in any case that improvement is the direct consequence of the remedy." Today medicine and surgery claim to effect a large measure of palliation in a considerable proportion of cases. No connection has yet been established between the clinical picture and the structural changes sometimes found in the muscles (lymphorrhages) or the thymus gland (enlargement, thymoma, or other abnormalities). But the aim of all modern treatments is either (centrally) to suppress the activity of the thymus or (peripherally) to restore the normal relations between acetylcholine and cholinesterase at the myoneuronal junctions. The extreme variability of the distribution and duration of spontaneous remissions and relapses makes it difficult to assess the effect of any but the most dramatically successful treatment. And, as LAURENT² points out, "Neostigmine" dosage alone is not a satisfactory criterion of progress: the patient's eagerness to report improvement, the misgivings aroused by references to "addiction," and (in cases treated surgically) the operative restriction of activities or change of residence, make this a thoroughly unreliable standard. Only objective technique providing a quantitative measure of severity and response to treatment is electromyography, which is now extensively used for this purpose in the United States and will no doubt be increasingly adopted here.

Suppression of thymus activity is attained either by X-rays or by surgical excision. VEITS³ who subjected most of his surgically treated patients to irradiation before thymectomy, found that many cases were temporarily improved by the X-rays and often the irradiation seemed to be as effective as the subsequent operation. However he was not primarily concerned with the value of irradiation. Other results suggest that patients treated by irradiation alone are unlikely to be any better after six months than they would have been without it, even the most optimistic observers do not claim improvement in more than 18%.

Much better results than this have been claimed for thymectomy, but the three recent British reports⁴ are somewhat disappointing—where the data are adequate for a proper assessment the results are poor, and where the results are said to be unequivocally satisfactory the data are incomplete. Furthermore the reports chiefly emphasise the improvement noted after many years, whereas if operative benefit is to be convincing it should occur reasonably soon after the operation. This did happen in 2 of VEITS's 18 patients, but because less than twelve months had elapsed since operation in 7 cases he considered it too soon to judge their improvement. KEYNES⁵ does not mention how long after operation he assessed improvement in his series. And his argument that in cases treated surgically the probability of lasting remissions would be extremely small on the basis of HARVEY's⁶ figures is not wholly convincing. The conclusions reached in these three surgical reports are at variance in important respects. Two find that thymectomy is more likely to be beneficial if there is X-ray evidence of the presence of a thymus; the third comes to the reverse conclusion. One finds that the prognosis is much better in early than in established cases; the others note no such correlation. One contends that operation is the treatment of choice in all but a few cases; another recommends that less than 50% should be operated on. One finds that patients of all ages have an equal chance of benefit; another strongly advises against operation if the patient is over 40. KEYNES advises early operation on account of "the 11.6% incidence of tumours the development of which should if possible, be anticipated," but none of these reports gives any example of a tumour appearing in a patient already known to have myasthenia gravis—indeed, most of the thymomas found had been present a long time before the beginning of symptoms. All in all the physician who reads these papers will probably remain unconvinced that surgery offers a better chance of improvement than medicinal treatment alone.

Of medical treatment it can be said at once that ephedrine and neostigmine are still the only remedies which offer substantial relief over long periods though several other drugs have lately been introduced. Ephedrine is commonly given in doses up to gr. 1½ twice or three times daily. Sleep may be impaired if the last dose is taken after 3-4 P.M., and in elderly patients the drug may cause difficulty in micturition. Ephedrine alone is seldom very effective, but it is often useful as an adjuvant to neostigmine. Neostigmine is given either by intra-

The solution can be stored in a rubber capped bottle with a connection from the stopcock to a needle piercing the cap, a second needle being inserted to allow air to be drawn into the bottle. Alternatively, the anticoagulant solution may be stored in a standard blood transfusion bottle and a giving set used to connect it to the apparatus.

In this way an entirely closed circuit is obtained, and any part of the apparatus can be flushed with anticoagulant solution without dismantling a single joint, and, after flushing, the solution can be ejected through the tube used for discarding the blood aspirated from the baby.

A small stand carries the syringe rigidly and is mounted with a screwed clamp to the any convenient table. When in position, the lies at an angle of 45° to the horizontal, thus that any air in the system ascends to the syringe and is not introduced into the infant's

The apparatus is manufactured by Messrs P Supplies Ltd, 83, Mortimer Street, London, W.1. I to thank Mr J. T. Burns of that firm for his in its production.

Reviews of Books

Disorders of the Blood

6th ed. Sir LIONEL WHITBY, C.V.O., M.C., M.D., F.R.C.P., D.P.H., regius professor of physic, University of Cambridge, C. J. C. BRITTON, M.D., D.P.H., physician and hematologist, Prince of Wales's Hospital, London. London J & A Churchill 1950. Pp 759 42s.

THE writers of a textbook on a subject that is rapidly growing have to steer a course between the Scylla of omitting new and relevant material, and the Charybdis of including new work that is denied or altered before the book gets into print. In this sixth edition, the authors have aimed at giving "a fair appraisal of the subject up to the end of 1949," and it will be agreed that they have made a very good selection of new material. The general shape of the book remains unchanged. There are 85 more pages, but much has been deleted. Four new plates, mostly of not very clear colour photomicrographs, are added, fortunately the former colour plates, which are better, are also retained. Nomenclature follows accepted English usage and has been standardised throughout the book, and the authors have sane views on the megaloblast question. Revision of detail has been remarkably complete: for example the standard haemoglobin is now given as 14.8 g per 100 ml, the use of intravenous iron is described, vitamin B₁₂ has its place, the section on myeloma has been adequately revised, and in splenic anaemia there is a good and balanced discussion of the problem of selecting the best treatment.

A really good short account of the complicated subject of blood-groups does not burke the question of the subgroups, either in the ABO or the Rh groups. A timely section on assessing the hazards of radiation workers is now included.

A few criticisms can be made. It seems odd to give 4½ pages to a discussion of the outmoded Arneth and similar counts, while allotting only 3 to a rather confusing account of blood-clotting. The description of some techniques could do with polishing: for instance, in red-cell counting, most laboratories now use the improved Neubauer ruling, and this should at least be shown; again, a method like the use of viper venom for estimating prothrombin-time—which is admitted to be unreliable—should be deleted from a standard textbook. These however, are minor points, and this edition maintains the reputation of the most readable textbook on the subject.

Eighty Thousand Adolescents

BRYAN H. REED, B.D. London Allen & Unwin 1950 Pp 188 12s 6d

THE Edward Cadbury Charitable Trust, which inaugurated this survey, has provided in its results much food for thought—more, perhaps, than in any comparable recent study. The book itself should be read, for the scope and diversity of the data obtained by visits to youth organisations and by individual questionnaire-filling makes them proof against adequate summary. Statistics cover most aspects of youth work, and many aspects of social behaviour, such as cinema going, reading, gambling, interests, and leisure. The standards of literacy and cultural interests are low by orthodox educational standards—though, judging by examination answers, a survey of literacy in preclinical students of medicine might give equally disconcerting results. In general, the extent to which adolescents succeed in

emancipating themselves from their environment through spontaneous associations, such as fire and pigeon clubs, no less than through organised organisations—is encouraging. The real problem is not one of literacy, interest, or the survey serves to underline at every point that the real need of all the youngsters, unattached to youth clubs, is for experience of in an integrated social society. The authors, in discussion of leadership and training for citizenship, fully aware that the adolescent problem belongs to anthropology rather than morals, and that it is cosmic reflection of the asocial adult society. To extent they are ready to criticise, fairly but pointedly the uniformed and disciplinary type of youth, which, from the anthropological point of view, very closely the response of power-centred adult to the insecurity of an asocial background. The case, as they realise, for seeing in the "five club" exhibits mutual and a more valuable manifestation of the highly organised youth movement which depends for cohesion upon discipline from above.

The religious background of the survey is now obtrusive, and is critically and informatively throughout. The authors contrive to be fair to every. Their awareness of the general sociological problem, its relation to questions of politics, economics, society structure is most praiseworthy. In view of closure of the Peckham experiment which aimed at integral family study of sociality, and which is sensibly criticised here, we might reasonably wish an extension of that awareness in official public health.

Office Orthopaedics

LEWIS COZEN, M.D., F.A.C.S., assistant professor orthopaedic surgery, College of Medical Evangelists, Angeles, London. Henry Kimpton 1950 Pp 237

Dr Cozen hints in his preface that his book is intended to guide the general practitioner in details of daily management of ambulatory orthopaedic patients which are often glossed over in larger textbooks, and it is certainly true that much useful information is to be found here on splints and strapping, plaster, local anaesthesia, and clinical examination. It is all catalogued in a rather uncritical and unsystematic manner, and the final section on differential diagnosis includes a few words on so many obscure conditions dragged in for the sake of completeness, that it is rather dreary reading. Some judicious pruning of it would make a second edition more acceptable.

Textbook of Biochemistry (5th ed. Philadelphia London W B Saunders 1950 Pp 609 30s) —Bynot trends in his specialty, and shifting the emphasis according to Prof Benjamin Harrow has been able to keep his book to the same convenient size yet thanks to dextrous sub a formidable list of additions have made their way in text. Among these are a new chapter on biological and many references to microbiological methods.

The Irish Medical Directory and Hospital Year 1950 (Dublin Parkside Press Pp 268 15s 6d) contains interesting forewords written by Dr Noel C. B. T.D., minister for health Republic of Ireland, and the Debra Parker D.B.E. M.P., minister for health and government of Northern Ireland. Additional items: the Dublin Hospitals Bureau, the Local Health Authorities of Northern Ireland, the Hospitals Management Association of Northern Ireland, and the National Blood Transfusion Association.

nine may make matters worse by causing pouring of saliva and pharyngeal mucus, if enough atropine is not given at the same time. Often, however, the practitioner is more interested in the management of the patient than in the disease. Many cases of myasthenia gravis—those described in our Disabilities series¹³ was an example—are not diagnosed until the patient has many months of mental anguish with the onset of hysteria. Then when the misconception is removed, the contemptuously critical attitude is engendered often changes to an over-optimistic commiseration which is even more disconcerting. A balance must be struck between the patient's tendency, or the prospect of indefinitely protracted illness, and the over-optimism, which invites the patient to disappointment. Complete remissions are possible even after long periods of severe disability, and the patient's interest should be directed in exploring variations in the amount and frequency of doses. The better-educated patient usually keeps himself fully informed about new medicines and will ask to try those that seem appropriate, this very natural and not necessarily neurotic reaction should not be lightheartedly discouraged.

Bather's Cramp

As a Frenchman bathes after a meal and drowns," André Maurois once said, "he is smitten with death, the Englishman may drown in just the same way, but his friends call it cramp and so the national honour is saved." It will be news to most that bather's cramp is an exclusively English ailment. But at this time of the year middle-aged men on our many beaches do gaze anxiously at their wives to assess the passage of postprandial time, and countless small children are restrained by their mothers from bathing too soon after meals, lest the onset of cramp overtake them. Yet sudden death in the water will inevitably mar some holiday and unless it will be attributed, by the lay public if not by the pathologist, to bather's cramp. The mere fact that the victim died while sea-bathing seems to be taken as excluding such other accidents as a fall, coronary-artery occlusion, and the other non-cramp causes of sudden death.

There are undoubtedly some cases where no clear pattern can be found at necropsy, and the pattern is usually the same. A healthy person, perhaps an accomplished swimmer, enters the water, appears to be enjoying his bath, and suddenly and silently he dies. Often he is dead before being recovered, and if he survives he generally remembers nothing about it. Occasionally consciousness may be lost immediately on entering the water. It is difficult to see how muscular cramp alone could disable him suddenly, without warning. Even if bereft of power in both legs an experienced swimmer can keep himself afloat by using his arms alone, crying for help the while.

And are swimmers any more liable to muscular cramp than other athletes? The cutaneous vasoconstriction induced by exposure to cold ought, physiologically, to ensure an improved muscular blood supply, it would indeed be ironical if the bather, swimming in brine, should die of the cramp attributed to sodium deficiency. Clearly some other explanation

must be sought. As an alternative to cramp, several other conditions have been postulated, including vagal inhibition, hypertensive encephalopathy, or the paralyzing pain of an acute disc prolapse, presumably induced by the occasional bather's unpractised version of the Australian crawl. Acute dilatation of the stomach, perhaps precipitated by swallowing seawater when the stomach is already full, is a further suggestion. In recent correspondence columns the sad demise of a favourite puppy has been tentatively attributed to a sudden attack of Charcot's laryngeal vertigo, brought on by falling into the water.

BOIGEY¹ has lately surveyed the physiological changes induced by cold bathing and attempted to explain these sudden deaths. The healthy young adult on entering cold water experiences a sudden stimulation accompanied by blanching of the skin and a sense of constriction in the chest. This soon gives way to a feeling of well-being which should normally persist long after the bath is over. If immersion is unduly prolonged, peripheral vasoconstriction may be succeeded by vasodilatation, and syncope may ensue. In some less fortunate people with unstable vasomotor control, the plunge into cold water leads to immediate headache, general muscle tightness, violent shivering, and a sickly pale cyanotic complexion. In BOIGEY's view, children are more subject to this reaction than adults, but those parents who are reduced to shivering wrecks when sharing their children's marine exploits will not agree. He supports the traditional English approval of cold bathing for young adults, but enjoins people over fifty to be cautious, because of the reactive hypertension induced by peripheral vasoconstriction. He has himself seen no less than 11 cases of hemiplegia beginning within an hour of cold bathing.

The part played by heavy meals shortly before bathing deserves critical examination. On general principles, strenuous exercise of any sort should be avoided till digestion is reasonably well advanced. Many of the holiday-maker's transient digestive upsets—"gastritis," diarrhoea, and vague dyspepsia—are undoubtedly due to neglect of this simple precaution. VERHOOGEN² advanced the ingenious explanation that some sudden postprandial deaths are due to anaphylaxis: sudden exposure to cold results in release into the general circulation of imperfectly digested protein derivatives, the delay in reaction being explained by the relatively slow passage of these substances through the gut wall. In other instances, he suggests, the anaphylactic reaction may be due to cold itself, and susceptible people might be detected by applying ice or ethyl chloride to the forearm and watching their reactions. This project may appeal to the ardent physiologist, but will gain little support from the rank and file, who go to the sea to enjoy themselves. The precaution of refraining from bathing immediately after a heavy meal is almost certainly wise, but that apart doctors can offer little useful advice to healthy subjects. A few will inevitably die as a result of strokes, cardiac catastrophes, vagal inhibition, cold anaphylaxis, or—just possibly—bather's cramp, but they will presumably die happy. And that is no mean achievement, these days.

muscular injection of 1-2.5 mg in solution or by mouth in 15-20 mg pellets. The dosage required varies widely. Some patients are kept comfortable and fit for full work on 60-100 mg by mouth daily, others need much more and must also have intramuscular injections. Patients have been known to take over 1000 mg by mouth and 7.5 mg by injection every day without developing toxic effects. But as a rule these side effects—intestinal colic, diarrhoea, nocturnal sweating, and salivation are the chief ones—necessitate a dose of atropine ($\text{gr} \frac{1}{100}$ by injection or 20-30 minims of tincture of belladonna by mouth) before each dose of neostigmine, and sometimes they are still so severe that the patient cannot take the full amount of neostigmine that he needs.

The other remedies fall into two groups (1) those of historic interest but of little value in regular treatment, and (2) those introduced so recently that their full effects have not yet been fully determined. The first group includes glycine, suggested by BOOTHBY⁶ in 1932 because it diminished creatine excretion, but this is now rarely used, and guanidine hydrochloride, introduced by DODD and his colleagues⁷ in 1938, and not now recommended, though it has slightly improved a few cases. Potassium lies on the borderline. LAURENT and WALTHER⁸ reported favourably on the effects of 10-50 g daily in divided doses, the few patients who can tolerate effective doses for long may find it useful in conjunction with neostigmine and ephedrine. Among the newer remedies of the second group there are three with strong cholinesterase inhibiting properties in animals. Di-isopropylfluorophosphate (D.F.P.)⁹ is not so effective as neostigmine, though it reduces the cholinesterase content of the plasma to zero promptly and for a long time. It is given in doses of 2-3 mg intramuscularly once or twice a week. Toxic side effects, similar to those of neostigmine, often prohibit its use, but its one advantage is that it improves power for conspicuously longer than neostigmine. Apparently neostigmine protects cholinesterase from deactivation by D.F.P., so when both drugs are being given at least $1\frac{1}{2}$ hours should elapse between doses of D.F.P. and of neostigmine. Hexa ethyltetraphosphate¹⁰ has similar effects when 10-12 mg is injected intramuscularly every three to five days, and has been used as an alternative for lowering the dose of neostigmine required. Two years ago, BURGEN and others¹¹ at the Middlesex Hospital introduced the third anticholinesterase drug—tetra ethylpyrophosphate (T.E.P.P.), which is intermediate in duration of action between neostigmine and D.F.P. Their report, and that of STONE and RIDER, showed that 8-12 mg of T.E.P.P. a day by mouth will completely relieve the symptoms in some cases and substantially reduce the requirement of neostigmine in others. But its use presents some difficulties. The drug is rapidly inactivated by water, so a stock solution in anhydrous propylene glycol has to be diluted with water or milk immediately

before being swallowed. A more serious is the narrow margin between the effective peptic dose and one that gives rise to toxic including convulsive seizures and severe cardiac, accompanied by depression of ST and low-voltage T waves in the electrocardiogram. Moreover, a dose that is well tolerated for a time later become toxic. As with D.F.P., the esterase inhibiting effect of T.E.P.P. is blocked by neostigmine, so neostigmine must not be given $1\frac{1}{2}$ hours of a dose of T.E.P.P. Lastly, we come to the pituitary adrenocorticotrophic hormone. Starting from the observations that this increases acetylcholine synthesis *in vivo*, that extracts inhibit acetylcholine synthesis, that it seems to cause a reduction in lymphatic tissue shrinkage of the thymus, and that removal of pituitary gland in rats produces myasthenic changes in the electromyogram, TORDA and WOLFF¹² gave 400 mg of A.C.T.H. in five days to 5 patients with myasthenia gravis, also continuing their usual dose of neostigmine. While taking the hormone all patients were worse and had various degrees of increased fatigue, menstrual bleeding, diarrhoea, colic, and hotness of the feet and hands. But ten days after the end of the course all were much improved, and they remained so for the three months of further observation, there was also an increase in acetylcholine synthesis and their electromyogram became more or less normal. Subsequent experience has confirmed this clinical improvement, though in one patient the intensification of symptoms persisted. To sum up for the two groups of drugs, only neostigmine and ephedrine have passed the experimental stage and can be relied on to relieve myasthenic symptoms with reasonable safety, there is no evidence that they have any effect favourable or adverse, on the underlying disease.

For the present, though he may consider adrenalectomy for a younger patient, the practitioner probably rely on these basic symptomatic remedies in most cases of myasthenia gravis. The following generalisations may be useful. Ptosis and diplopia often respond extremely well in the early stages of treatment. If diplopia persists, it may be worse instead of relieving it with very high dosage of neostigmine, to get the patient to wear a frosted glass in front of one eye from time to time. Dysphagia also usually responds satisfactorily if the doses are timed to anticipate meals and if these are suitable in type and size. In severe cases or during relapses a nasal tube may be left in situ. A case of respiratory distress should never be ignored because the patient's colour remains good and pulse and respiration are not very quick, the patient's own sense of effort and distress is often a more reliable warning of impending trouble. A sudden exacerbation of weakness in the limbs may prevent the practitioner administering his dose of neostigmine, even though he has it ready in a syringe, he should therefore warn his friends and associates of this possibility and tell them what to do for it. Acute exacerbation of respiratory weakness may call for artificial respiration in a Drinker apparatus at very short intervals. A sudden panic-stricken increase in the dose

variations which exist in the services supplied by local health authorities." General criteria would help to check abuse. "It is clear," says the Ministry of Health, "that the Ministry of Health are paying public health to some local health authorities for ambulance services in circumstances where other local authorities might have provided them." The Ministry should co-operate in getting out this unevenness, after consultation it should lay down rules for the use of ambulances. At present, if the more striking differences in the authority are not provided before the service may be used. The committee is favourably impressed by the practice, followed in some parts, whereby drivers are forbidden to carry one (except in an emergency) without a medical certificate, and it also applauds the London County Council's general rule that hospitals rather than doctors should order ambulances. In London this has prevented patients being carried to hospitals where no bed is to be had.

The committee recommends that before admitting a patient from a distant place hospitals should demand a certificate that the necessary treatment cannot reasonably be obtained at a nearer hospital, and that for long distances the railways might more often be used. It notes that outpatients sometimes continue to be carried and from hospitals after they have become fit to travel by ordinary means. The report urges all large hospitals to appoint a transport officer, who will be directly responsible to the senior administrative officer. Finally, it proposes a tightening up in the regulations for the use of the voluntary Hospital Car Service.

ANTIMALARIAL DRUGS

It is not surprising that W.H.O.'s expert committee on malaria finds that no existing antimalarial drug has all the desired qualities. Their ideal drug would be a causal prophylactic against all species of human malaria parasites, would have a definite curative value and low toxicity, and would be cheap. If such a product has not yet been produced, one must remember that different geographical strains of malaria parasites differ in their reactions to both prophylaxis and therapy, and that the degree of premunition of the host may affect their action. The efficacy of specific drugs is by no means the same everywhere.

As the committee say, the treatment of malaria is firmly connected in the public mind with the use of quinine, and for malarial emergencies injections of quinine are still generally recommended. The evidence here adduced in favour of their opinion that certain synthetic drugs may possibly be equally effective for their purpose is not perhaps entirely satisfactory, and the same is true of the observations they quote on restriction of the field of vision attributed to a toxic action of quinine. These observations were made by Oatner¹ et al.² in a United States penitentiary where 17 white male volunteer prisoners took 0.5 g quinine sulphate daily, and 5 others 0.25 g, for twenty-five consecutive days. Later 3 were found to have contracted central fields, but, as their eyes were not examined before treatment, their vision may possibly have been abnormal previously. Quinine amblyopia as such is generally considered exceedingly rare and this isolated American observation conflicts with experience in West Africa and other parts of the tropics where Europeans have been in the habit of taking large doses of quinine for many years without untoward effect. In linking quinine with the causation of blackwater fever the committee have, of course, ample precedent. But it could be wrong to assume that blackwater has dis-

appeared from West Africa since the almost universal application of mepacrine (atebrin), first as a causal prophylactic and later as a remedy for subtertian malaria. There seems, in fact, to be no evidence that the incidence of blackwater after quinine is greater than that after mepacrine therapy.

On mepacrine in general perhaps it would be true to say that the committee tend to say more about its virtues than its vices. Thus they do not comment on the risk of mental disturbances arising from the increasingly high doses that have become customary since the war, or on the lichenoid eruptions of the skin it sometimes produces. Their conclusions about chloroquine and closely related compounds are necessarily rather vague, because relatively few systematic observations have been made on treatment with this drug, but they allow themselves to state that as a suppressant its action is unsurpassed by any other. This is especially true in *Plasmodium vivax* infection, which can be completely suppressed by giving 0.5 g of chloroquine once a week for six months. Chloroquine does not stain the skin or eyes and seems to have no undesirable side effects, but it has a smaller margin of safety than proguanil (Paludrine³) and is relatively expensive. On proguanil there now seems to be some real unanimity. Its main merit is that it is a causal prophylactic against *P. falciparum*—a property not possessed by quinine, mepacrine, or the 4 aminoquinolines. Its therapeutic action differs in different parts of the world and in different races, but all agree that it is slower in action than quinine, mepacrine, or chloroquine and therefore cannot be relied on in the treatment of malarial emergencies where speed is essential. Moreover, when given alone, it cannot be relied on to cure infection by certain strains of *P. falciparum*. Another disadvantage of proguanil is the ease with which malaria parasites become resistant. Apparently this resistance is increasing especially in West Africa. Of the various remedies considered pamaquin and the related 8 aminoquinolines are the most toxic and hence have little practical application. Pamaquin appears to be the most poisonous, but is closely followed by pentaquine and isopentaquine.

The committee's very thorough report also covers the organisation of training, and antimalarial measures in general, on all of which valuable advice is offered.

TUBERCLE BACILLI IN THE C.S.F.

THE finding of tubercle bacilli in the cerebrospinal fluid does not necessarily mean that there is a diffuse tuberculous meningitis. McGregor and Green¹ in 1937 cultured tubercle bacilli from the C.S.F. of patients with primary tuberculosis in whom there was no clinical or pathological evidence of meningitis. They also demonstrated by animal inoculation the presence of tubercle bacilli in the C.S.F. of three patients with positive tuberculin skin tests and the clinical picture of meningeal irritation, without evidence of tuberculosis elsewhere. Lincoln² in 1947 drew attention to the occurrence of "serous tuberculous meningitis" during the course of a primary infection. Tubercle bacilli were not found in the C.S.F. in her cases. The fluid was under increased pressure and its cell-count was raised, but it was otherwise normal. In two patients who died after recovery from the meningitis post mortem examination showed healed non-specific meningitis. The view that caseous tuberculous meningitis arises by rupture of cortical foci into the subarachnoid space was put forward in 1933 by Rich and McCordock.³ Lincoln suggested that the clinical picture in "serous tuberculous meningitis" was due to perifocal reactions around unruptured tuberculous lesions in the brain.

Annotations

HOSPITAL APPOINTMENTS

Up till now in non teaching hospitals the appointment of registrars has been the responsibility of the hospital management committee. But the posts of registrar and senior registrar are important steps in the training of consultants, and experience has shown that the universities, the medical schools, and postgraduate institutions could with advantage be drawn more closely into the task of selecting the right men for these jobs. A change in the present procedure would also, as we suggested last year,¹ foster a healthy interchange between teaching and non teaching hospitals and allow the consultant in training to move more freely between the hospitals in a region. On all these heads the transfer of responsibility for these appointments to the regional hospital boards² on Sept. 1 will therefore be welcome. The hospital management committees will, of course, still play an important part in selection and will continue to appoint the junior registrars. No change will be made in the arrangements for the payment of the registrars' salaries in the present financial year.

These registrar posts will not come within the scope of the committees that advise the regional hospital boards on the appointment of consultants, and the Ministry is laying down no precise machinery for making registrar appointments. It is suggested, however, that the selection might appropriately be made by a committee consisting of a standing nucleus of one medical and one lay member appointed by the regional hospital board, one lay member appointed by the board of governors, and two medical members appointed by the university. To these, two or three members would be added by the hospital concerned, one of whom would normally be the registrar's future chief. A member of the specialty concerned would also be appointed by the regional hospital board or by the university.

Some smaller changes have been made in the procedure for the appointment of fully fledged consultants,³ but these mostly concern the powers and composition of the advisory committees which submit recommendations to the boards. Some of these appointments—such as of members of professorial units who receive no remuneration from hospital boards, some clinical teachers, some research workers, retiring consultants continuing work in an honorary capacity, and distinguished visitors from overseas—will no longer be considered by these advisory committees, though the actual appointment will still be made by the boards. The duration of the appointment need no longer be stated in an advertisement for one of these senior posts. When there is no applicant of consultant standing the advisory committee may no longer recommend that one of the candidates should be appointed with the grade of senior hospital medical officer. The constitution of these committees has also been slightly varied—for a teaching hospital the committee will now have 8 members. Members from outside the region who represent the specialty concerned will be appointed after consultation with one of the Royal Colleges.

The procedure for the appointment of consultants was designed with the laudable intention of preventing inbreeding. At the time we foresaw⁴ that it might bring new difficulties to replace those it avoided, and at least one London teaching hospital has found that a mechanism which looks fair and easy on paper is in practice clumsy and expensive in time, labour, and money. The new constitution will do nothing to ease this administrative burden.

THIOSEMICARBAZONE IN LEPROSY

The German drug 'Thiosemicarbazone' or 4-aminobenzaldehyde thiosemicarbazone, is now extensively tested in the United States and thus as a treatment for tuberculosis, in which it seems about as active as *p*-aminosalicylic acid (P.A.S.).¹ P.A.S., too, it is being used both alone and in addition to streptomycin. Since other drugs that inhibit growth of *Mycobacterium tuberculosis* have proved effective the closely similar acid fast organism, *Mycobacterium leprae*, Dr Gordon Ryrie, of the British Empire Leprosy Association, has undertaken a clinical trial of thiosemicarbazone in leprosy. Of the 10 cases so far 8 were examples of the virulent lepromatous type two had chronic tuberculoid leprosy. The preliminary results, reported on p. 286, seem promising though as Dr Ryrie freely admits, the value of the drug will be assessed after only four months' study on 10 patients. All have improved clinically and most have shown bacteriological improvement. In Dr Ryrie's view they have improved more rapidly than they would have done with sulphonamides, and there has been less depression. The dose of thiosemicarbazone, given in 25 mg tablets of Messrs Boots's preparation 'Thiacetazone,' was gradually increased to 150 mg daily. At this dose level no toxic effects were recorded but the German workers have found the drug potentially toxic and have reported anorexia, malaise, headache, vomiting, anaemia, conjunctivitis, jaundice, and granulocytopenia in tuberculous patients given the drug for a long period. The leprosy patients may have experienced side effects because they were not treated long enough and did not have a second course of the drug—drug reactions occur only when there has been a previous course to produce sensitisation. Toxic effects would be particularly likely to arise in poorly nourished, anaemic and infested lepers, and they may well be troublesome when a larger group of patients is treated.

AMBULANCES

The free ambulance service provided under the National Health Service Acts is operated in England and Wales by local health authorities, which receive half of the cost from the Ministry of Health. In Scotland, on the other hand, the service is operated entirely by the Department of Health, and the whole cost borne centrally. The Select Committee on Estimates in reviewing these services,² points out that none of the cost falls on the Scottish ratepayers, and in effect the ambulance service in Scotland is mainly paid for by the taxpayers of England and Wales.

For the present financial year the total cost of the ambulance services to the nation is estimated at £7,086,000. The cost is rising as the demand increases. In England and Wales the number of patients carried in ambulances and sitting case cars rose during 1949 from 365,859 in January to 488,890 in December. The Select Committee finds that a large local health authority needs to maintain one ambulance or sitting-case car for about 10,000 people, but in a small and sparsely populated area the proportion may be much higher; thus in December, 1949, Huntingdonshire required one ambulance or car for every 3765 of its population. In England and Wales as a whole about 10% of the population are transported in this way each year, but local differences are wide. There are also wide differences in running costs among three authorities which submitted evidence on this point, the cost per mile run ranged from 2s to 3s. The committee, while advocating more centralised control, suggests that the Ministry of Health should interest itself more in the

INTERNATIONAL CONGRESS OF PÆDIATRICS

Sixth International Congress of Pædiatrics, Zürich from July 24 to 28, was attended by over representatives from 56 countries. The largest was from the United States, but the highest from a country outside Switzerland came from Italy, over half of whose pædiatricians attended. Arrangements were carried out with characteristic efficiency, and there were numbers of voluntary workers, including many students, to show the members, answer questions, and generally ensure that the congress went smoothly.

In the opening session, the Kongresshaus was decorated with the flags of the nations taking part, delegates were welcomed by Prof G. FANCONI, president of the congress. He spoke first in Italian, then in English, German, Italian, and Spanish, and that the importance of international cooperation was especially realised in Switzerland, a small country surrounded by great neighbours and having four official languages of her own. He was glad to see that any German speaking doctors had come, and he said that the congress might be a means of helping international pædiatrics, which, like other branches of medicine, had suffered such a setback under the régime. He regretted that the Russian delegates did not, after all, being able to come.

Speeches of welcome were also made by Dr PH. ETTER, official councillor, and Dr MARTIN BODMER, vice-president of the International Committee of the Red Cross. There followed a pleasant ceremony when honorary doctorates were conferred by the dean of the Faculty of Medicine on Dr Arvid Wallgren, professor of pædiatrics at the Karolinska Institutet, Stockholm, and on Dr James L. Gamble, professor in the Harvard University Medical School. Dr Gamble, unfortunately, was prevented by illness from receiving his degree in person.

Dr HENRY F. HELMHOLTZ (Washington) put forward a plan for an international pædiatric organisation, and at the meeting of national representatives later in the week proposals were adopted, with slight modifications, that the International Pædiatric Association was formed. Its objects will be to promote closer relations between pædiatricians of all countries by holding an international congress every three years, to promote the spread of pædiatric knowledge, and to cooperate with other agencies concerned with the improvement of child care, pædiatric education, and research in all parts of the world. The papers at the opening meeting were read by Dr ROBERT DEBRÉ (Paris) on *streptomycin* and by Dr F. GOMEZ (Mexico), who described the successful treatment of malnutrition with a diet of purely vegetable food.

SOCIAL PÆDIATRICS

In the second plenary session, held at the end of the congress, Prof ALAN MONCRIEFF (London) emphasised the importance of morbidity as well as of mortality figures in preventive medicine, and quoted those of Smellie from the Children's Hospital, Birmingham. Respiratory infections are now the most frequent in infancy, burns and accidents the commonest cause of death in older children, so preventive measures should be directed especially against these groups. Turning to the psychological side of social pædiatrics, Professor Moncrieff mentioned the categories of *Children in Danger*—orphans, those from broken homes, neglected, and in moral danger. He emphasised that each group is numerically very large, and told delegates what was being done in this country under the Children's Act and by various voluntary agencies to help these children.

Later in the session, Dr MARTHA ELIOT, deputy director general, World Health Organisation, gave an account of the many ways in which W.H.O. is helping pædiatrics and child health. Prof ERICH ROMINGER (Kiel) spoke on *infant dystrophy*, and Prof GINO FRONTALI (Rome) on the *endothelial constitution*, describing observations on the cutaneous capillaries in purpura, scarlet fever, nephritis, and rheumatism.

Sectional Proceedings

The remaining papers were given in fourteen sections, of which four or five were taking place simultaneously, in the lecture rooms of the Polytechnikum. Though the scope of the congress was comprehensive, in so far as there was any emphasis it was on preventive pædiatrics. Dr CICELY WILLIAMS (New Delhi) spoke on *child health in the tropics*, and papers on the *care and feeding of premature infants* were read by Dr F. J. W. MILLER (Newcastle upon Tyne), Dr ROBERT COLLIS (Dublin), and others. The *prevention of neonatal mortality* was the subject of another discussion, to which Dr MARY V. CROSSE (Birmingham) contributed, and representatives of ten different countries spoke on the prevention of disease among children of all ages. Prof J. M. SMELLIE (Birmingham) pointed to the decline in the death rate from gastro enteritis in England and Wales during the last fifty years, and said that the principal causes of infant mortality in order of frequency are now prematurity, bronchitis and pneumonia, atelectasis and birth injury, enteritis and diarrhoea, and congenital malformations. Though there has been a great reduction in the mortality rate, the speaker estimated that a further 15,000 babies could be saved each year by the fullest application of obstetric and pædiatric knowledge.

Sir JAMES SPENCE (Newcastle upon Tyne), speaking on the effect of socialisation and social institutions on pædiatrics, enumerated the social forces altering the function of the family and diminishing the responsibility of the parents and considered their effects on the welfare of children. Also the effect on the doctors themselves of increasing State control of education must not be forgotten.

In a discussion on *erythroblastosis*, Dr LOUIS K. DIAMOND (Boston), dealing with the prevention of kernicterus, said that he was not now in favour of the induction of premature labour unless there had been several stillbirths previously. Dr P. L. MOLLISON

Polytechnikum where the discussions were held

More recently Choremis and his colleagues^{4,5} in Athens have reported similar observations. Tubercle bacilli were cultured from the C.S.F. of patients with acute tuberculous adenitis or milary tuberculosis even in the absence of signs of meningeal irritation. They also found tubercle bacilli in the C.S.F. of children recovering from tuberculous meningitis who had received intrathecal streptomycin and were regarded as clinically cured. This differs from the report of Smith, Vollum, and Cairns⁶ who did not detect tubercle bacilli in the C.S.F. by culture after the 29th day of treatment in those patients who survived. Choremis and his colleagues look upon tuberculous meningitis as having three phases—the subclinical, in which tubercle bacilli are present in the C.S.F. without evidence of meningitis, the stage of clinical meningitis, and the phase of recovery following streptomycin therapy in which bacilli are still present in the fluid but there is no clinical evidence of meningitis. They consider that the full development of tuberculous meningitis requires not only the specific histological changes in the meninges but also “secondary perifocal inflammatory reactions”.

It seems that the many factors concerned in the pathogenesis of tuberculous meningitis are still imperfectly understood. Both Lincoln and Choremis postulated focal hypersensitivity reactions around the aseptic lesions in the brain or meninges to explain the phenomena they had observed. It is interesting in this connection to recall that Choremis,⁷ who claimed good results with smaller doses of streptomycin than had previously been reported, combined the antibiotic attack with tuberculin therapy. The extraordinarily interesting results now obtained by Dr Smith and Dr Vollum with tuberculin are described in our present issue.

CHANGES IN THE POISONS LAW

When drugs are issued in ampoules it is customary for the makers to include a little more than the usual dose—e.g., 1.1 ml. in a 1 ml. ampoule—to allow for wastage in withdrawal. This practice is now to be regularised by an amendment to rules 7 and 12 of the Poisons Rules, 1949, by which a signed order or prescription for a medicine packed in ampoules may state either the total amount to be supplied or the total amount intended to be administered. The Poisons List Order, 1950, and the Poisons Rules, 1950,⁸ which will come into force on Sept. 1, also make the following additions to part I of the Poisons List and the first schedule.

Alphaprodine *

The anti-histamine drugs antazoline, diphenhydramine, 3-di-n-butylaminomethyl 4,5,6-trihydroxyphthalide, phenidamine, and tetra-substituted N derivatives of ethylene diamine or propylenediamine.

Betaprodine *

Di-isopropyl fluorophosphonate

Hydroxypethidine *

Isoamidone *

Ketobemidone *

Methadol *

Methadyl acetate *

Polymethylenebis(trimethylammonium salts)

Phenadoxone *

Preparations of anti-histamine substances intended for external application are exempted from the poisons requirements. Except in these preparations, the anti-histamine substances,* and polymethylenebis(trimethylammonium salts), are added to the fourth schedule, and

so may only be sold on prescription. Medicines containing di-isopropyl fluorophosphonate that are made ready for the internal or external treatment of ailments must be labelled “Caution. This preparation should be administered only under medical supervision. The vapour is dangerous”.

RHEUMATOLOGY AT THE ROYAL FREE

LONG waiting lists for beds in hospital tell rheumatic patients no less than the rest of the. The report of the Royal Free Hospital's rheumatism unit for 1949 notes that some women with rheumatoid arthritis deteriorate so much while for admission that by the time a bed can be found their condition is almost hopeless. On the other hand, cases which look similar may show no recovery during the waiting period that by the time a bed falls to them they no longer need it. Women in this unit, have to wait longer than men, for five times as many of them attend the outpatient department, there are only half as many beds for them as for men. The average waiting time for a woman is 18 months, but some have had to wait, the report runs, for more than a year. What is needed is evidently some means of telling at an early stage which cases are going to improve anyway, and which need intensive treatment to prevent deterioration.

During 1949, 594 new and 9097 old patients attended outpatient sessions, and 204 cases were admitted to the wards—almost the same number as in 1948. Comparison of the two years shows that the number of cases of rheumatoid arthritis admitted fell off slightly in 1949, and the results were slightly poorer than in 1948. But the good results obtained with ankylosing spondylitis in 1948 were maintained and exceeded in 1949. Of the 18 cases admitted in 1948 and fewer than 13 returned to work, and the other 5 improved. These results, we are told, were not easily obtained, being achieved in many cases, only after the patient had been in hospital for a long time, by the combined work of the unit and the radiology department. Results in osteoarthritis were much the same in each of the two years, about a third of the patients returning to work, while the remaining two thirds needed improvement. Many beds were blocked by cases needing nursing care but not benefiting from hospital treatment, and unlikely to do so, and the report speaks feelingly of the need for more beds for the chronic sick.

The outlook for chronic rheumatism is commonly thought to be gloomy, and it is therefore inspiring to read that only a small proportion of cases had relapsed within two years of treatment. In 85% of cases, as found by follow up, the improvement resulting from treatment in the unit had been maintained. Moreover rheumatic patients are often capable of readmission and a return to work. When a group of 25 patients from the rheumatology wards referred to the disablement resettlement officer were compared with a group of 23 patients referred from the general wards, the likelihood of getting a patient back to work was (allowing for the fact that the rheumatic patients were on an average 9 years older) about equal in the two groups. Research is going forward on the use of controlled force in the treatment of flexion deformity of the knee and into the mechanism of ulnar deviation of the finger. The degradation of hyaluronic acid, characteristic of almost all rheumatic diseases, is being studied in relation to the levels of ascorbic acid and alkaline phosphatase in the synovial fluid, and the small quantity of adrenocorticotrophic hormone in the hands of the unit is to be used in conjunction with this work. Cortisone remains for this and many other units, out of reach.

Prof W. E. LE GROS CLARK, F.R.S., who holds the chair of anatomy in the University of Oxford, and Prof F. G. YOUNG, F.R.S., who holds the chair of biochemistry in the University of Cambridge, have been appointed to be members of the Medical Research Council from Oct. 1.

INTERNATIONAL CONGRESS OF PÆDIATRICS

Sixth International Congress of Pædiatrics, Zürich from July 24 to 28, was attended by over representatives from 56 countries. The largest was from the United States, but the highest proportion from a country outside Switzerland came from Italy, over half of whose pædiatricians attended. Arrangements were carried out with characteristic efficiency, and there were numbers of voluntary, including many students, to show the members answer questions, and generally ensure that everything went smoothly.

In the opening session, the Kongresshaus was filled with the flags of the nations taking part. Delegates were welcomed by Prof G. FANCONI, president of the congress. He spoke first in Italian, then in English, German, Italian, and Spanish, and that the importance of international cooperation was specially realised in Switzerland, a small country surrounded by great neighbours and having four official languages of her own. He was glad to see that many German speaking doctors had come, and he said that the congress might be a means of helping paediatrics, which, like other branches of medicine, had suffered such a setback under the régime. He regretted that the Russian delegates not, after all, been able to come.

Speeches of welcome were also made by Dr PH. LUTER, municipal councillor, and Dr MARTIN BODMER, vice-president of the International Committee of the Red Cross. There followed a pleasant ceremony when honorary doctorates were conferred by the dean of the Zurich Faculty of Medicine on Dr Arvid Wallgren, professor of pædiatrics at the Karolinska Institutet, Stockholm, and on Dr James L. Gamble, professor in the Harvard University Medical School. Dr Gamble, unfortunately, was prevented by illness from receiving his degree in person.

Dr HENRY F. HELMHOLTZ (Washington) put forward a plan for an international pædiatric organisation, and at the meeting of national representatives later in the week proposals were adopted, with slight modifications, and the International Pædiatric Association was formed. Its objects will be to promote closer relations between pædiatricians of all countries by holding an international congress every three years, to promote the spread of pædiatric knowledge, and to cooperate with other agencies concerned with the improvement of child care, pædiatric education, and research in all parts of the world. Other papers at the opening meeting were read by Dr ROBERT DEBRÉ (Paris) on streptomycin and by Dr F. GOMEZ (Mexico), who described the successful treatment of malnutrition with a diet of purely vegetable origin.

SOCIAL PÆDIATRICS

At the second plenary session, held at the end of the week, Prof ALAN MONCRIEFF (London) emphasised the importance of morbidity as well as of mortality figures in preventive medicine, and quoted those of Smellie in the Children's Hospital, Birmingham. Respiratory infections are now the most frequent in infancy, but burns and accidents the commonest cause of death in older children, so preventive measures should be directed especially against these groups. Turning to the psychological side of social pædiatrics, Professor Moncrieff mentioned the categories of Children in Trouble—orphans, those from broken homes, neglected children in moral danger. He emphasised that each group is numerically very large, and told delegates what was being done in this country under the Children's Act, and the various agencies to help these

Later in the session, Dr MARTHA ELIOT, deputy director general, World Health Organisation, gave an account of the many ways in which W.H.O. is helping pædiatrics and child health. Prof ERICH ROMINGER (Kiel) spoke on infant dystrophy, and Prof GINO FRONTALI (Rome) on the endothelial constitution, describing observations on the cutaneous capillaries in purpura, scarlet fever, nephritis, and rheumatism.

Sectional Proceedings

The remaining papers were given in fourteen sections, of which four or five were taking place simultaneously, in the lecture rooms of the Polytechnikum. Though the scope of the congress was comprehensive, in so far as there was any emphasis it was on preventive pædiatrics. Dr CICELY WILLIAMS (New Delhi) spoke on child health in the tropics, and papers on the care and feeding of premature infants were read by Dr F. J. W. MILLER (Newcastle upon Tyne), Dr ROBERT COLLIS (Dublin), and others. The prevention of neonatal mortality was the subject of another discussion, to which Dr MARY V. CROSSE (Birmingham) contributed, and representatives of ten different countries spoke on the prevention of disease among children of all ages. Prof J. M. SMELLIE (Birmingham) pointed to the decline in the death rate from gastro enteritis in England and Wales during the last fifty years, and said that the principal causes of infant mortality in order of frequency are now prematurity, bronchitis and pneumonia, atelectasis and birth injury, enteritis and diarrhoea, and congenital malformations. Though there has been a great reduction in the mortality rate, the speaker estimated that a further 15,000 babies could be saved each year by the fullest application of obstetric and pædiatric knowledge.

Sir JAMES SPENCE (Newcastle upon Tyne), speaking on the effect of socialisation and social institutions on pædiatrics, enumerated the social forces altering the function of the family and diminishing the responsibility of the parents and considered their effects on the welfare of children. Also the effect on the doctors themselves of increasing State control of education must not be forgotten.

In a discussion on erythroblastosis, Dr LOUIS K. DIAMOND (Boston), dealing with the prevention of kernicterus, said that he was not now in favour of the induction of premature labour unless there had been several stillbirths previously. Dr P. L. MOLLISON

Polytechnikum where the discussions were held

(London) spoke on the assessment of the severity of haemolytic disease of the newborn, and Dr JOHN MURRAY (London) on the inhibition of haemagglutination by fatty extracts from blood and other tissues.

In the section on diarrhoeal diseases Dr DOROTHY H. ANDERSON (New York) gave an account of the differences between coeliac disease as seen today and as classically described by Gee. Dr W. K. DICK (The Hague) found that, whereas wheat and rye flour caused deterioration in a group of patients with coeliac disease, their replacement by maize or rice flour and wheat or maize starch was followed by a return of appetite and lessening of steatorrhoea. Dr H. A. WYERS (Utrecht) described observations by van de Kamer and himself in which the coefficients of absorption of saturated and unsaturated fatty acids were determined daily in coeliac disease. Wheat flour induced a high excretion of both and it was found that, on a diet containing wheat flour and poor in saturated fatty acids, the amount of the latter excreted was actually greater than that ingested. The difficulty in coeliac disease could not therefore be merely one of absorption, and a disturbance of intermediary metabolism was postulated.

Of great interest were the discussions on the prevention and treatment of virus, bacterial, and protozoal diseases. Dr JOSEPH STOKES (Philadelphia) mentioned the possibility of immunisation by the administration of attenuated virus by natural routes instead of by injection, and Dr F. O. MACCALLUM (London) gave an account of acute aseptic meningitis. Dr T. F. MCNAIR SCOTT (Philadelphia) described the work of his virus diagnostic laboratory, and Dr PHILIP EVANS (London) spoke on poliomyelitis following injections. Dr RALPH V. PLATOU (New Orleans) and others discussed the treatment of congenital syphilis in a session held jointly with the Union Internationale contre le Péri Vénérien, which was also meeting in Zürich. The paediatric uses of 'Aureomycin' and the newer antibiotics were detailed by Dr SAMUEL KARLITZ (New York), and Dr SIDNEY ROSS (Washington) spoke on 'Chloromycetin'.

Dr GEORGE W. THORN (Boston) opened a symposium on Adrenocorticotrophic Hormone and 'Cortisone,' and Dr RUSTIN MCINTOSH (New York) spoke on their effects in the nephrotic syndrome. There were contributions also from Finland, the Netherlands, and Denmark.

In the section on surgery in childhood, interest naturally centred on neurosurgery and thoracic surgery. Prof DOROTHY S. RUSSELL (London) gave an account of the pathology of hydrocephalus and Prof NORMAN DOTT (Edinburgh) of its surgical treatment. Dr JAMES H. HUTCHISON (Glasgow) spoke on the management of bronchiectasis of tuberculous origin, and Mr T. HOWES SPENCER (London) on the surgical treatment of bronchiectasis.

Dr HELEN TAUSSIG (Baltimore) described the clinical manifestations of congenital heart malformations amenable to surgery. Dr SIGURD ERIK (Oslo) spoke on the radiology of these malformations, Dr ANDRÉ COURNAUD (New York) on cardiac catheterisation and Dr AGUSTÍN CASTELLANOS (Havana) and Dr JOHN LIND (Stockholm) on angiocardiography. Dr EDGAR MANNING (Stock-

holm) gave an account of the postoperative course of 77 cases of morbus caeruleus and also read a paper by Dr C. CRAFOORD (Stockholm) on the surgical treatment of coarctation of the aorta. In the discussion which followed, Dr TAUSSIG and Mr HOLMES SELLORS gave the postoperative results, and the indications for pulmonary valvulotomy were discussed.

In the surgical section other papers were by Dr ORLA SWENSON (Boston) and Dr PHILIP SANDBLOM (Stockholm) on the surgery of malformations of the oesophagus. Dr Swenson also dealt with *rectosigmoidectomy* and *Hirschsprung's disease*, and Dr MARTIN BODIAN (London) with the pathology of this condition.

In the section on neurology and psychiatry, Dr MILNER CRAIK (London) spoke on Heller's dementia and a number of papers on electroencephalography were given, including one by Dr DENNIS HILL (London). There were also a number of British discussions on cerebral palsy, with contributions by Dr LAURETTA BRIDGER (New York), Dr PHILIP EVANS, Prof D. R. MACCATMAN (Leeds), Prof N. B. CAPON (Liverpool), and Dr O. D. S. AUSTIN (Cardiff).

The remaining communications included papers by Dr C. F. DENT (London) on disorders of amino-acid metabolism, and by Prof A. ST. G. HUGGITT (London) on placental causes of foetal abnormalities and the like. Dr JACK METCALF (Boston) spoke on the results of clearance techniques in the nephrotic syndrome, and Dr BERNARD SCHLESINGER (London) on the blood and bone marrow findings in Still's disease.

Exhibitions and other Activities

Over 200 demonstrations were given in the gymnasium, the Kantonschule, and it would have been even to spend the whole week admiring and studying them.

From this country were exhibits by BICKEL HICKS, BAAR and DOUGLAS (Birmingham) on the Debré-Le Janconi syndrome and by BODIAN (London) on Hirschsprung's disease. R. J. A. DEAN and McCABER and WILSON (Cambridge) presented the results of studies on nutrition, growth, and diet (London) gave a demonstration, and showed a film of the 'pop show' technique of pure audiometry. LIGHTWOOD and PAYNE (London) had an exhibit of 22 cases of infantile renal acidosis and SMALLWOOD (Oxford) one of meningitis due to gram-

Surgical demonstrations were given by DENIS (London) on the treatment of various congenital and by HOLMES SELLORS (London) on ectopic lung pulmonary arteries

he other exhibits, those of Cocchi (Florence) on logical pathology of the cerebrospinal fluid and of (Boston) on electrophrenic respiration attracted attention

programme of excursions and visits included the Kinderspital and the new Kantonsspital refugee orphan children's village Pestalozzi at The social arrangements included a steamer lake of Zürich, and a dinner followed by folk dancing, while there was a full programme of s and "guidances" for the ladies

Those who know best the lakes and mountains of Switzerland may have been surprised to find how beautiful her largest city is also, the spaciousness, the abundance of trees and flowers, and the lakeside setting made a perfect background for a memorable congress. Members will remember above all the kindly hospitality of the Swiss, who received so many into their homes and those who worked so hard to make the congress a success—Prof Fanconi the distinguished president, Dr Zellweger the general secretary, Dr Gasser chairman of the exhibitions, and Dr Rossi who had the enormous task of arranging accommodation.

The next International Congress of Paediatrics will be held in Havana in 1953 under the presidency of Prof Félix Hurtado.

FUNCTIONAL COSTING FOR HOSPITALS ON A "STANDARD" BASIS

D. M. LIVOCK
A. C. A.

ARD costing is an accounting technique whereby of any enterprise can be compared with a fixed—the standard cost—and the reasons for any from that standard are shown in relation to all nts of the cost. It combines the usual financial ng with information about current costs, and it learly the reasons for the difference between cost and the standard. In the past standard as been applied in this country solely in industry been found of great value to management as a of control. Probably the full application of the o hospitals is impossible, but there is no reason underlying principles should not be adapted tal finance.

ow widely acknowledged that functional depart costing will enable comparisons to be made the cost of similar services given in similar s. (For example, the cost of feeding a patient not vary greatly from hospital to hospital, and rison of the cost of a unit of heating should give ming information on the economics of the different s in use.) But the defect of departmental cost- method of control is that it does not distinguish a variable and fixed expenditure, and estimates n past departmental cost are entirely vitiated ges take place in the usage of the department re based on standards it would give departmental d at the same time enable budgets to be adjusted current changes in the volume of service given.

A PRACTICAL DEMONSTRATION

xperiment in departmental costing on a standard is been started in coöperation with the Nuffield al Hospitals Trust in a provincial teaching hos. Here it happened to be desirable to know the each ward and the system as applied is more ted than would be necessary in other teaching s, and certainly in non-teaching hospitals. A rtmental costing system had been in use at the for the past ten years, and the introduction ndard was fairly simple, since all the relevant ion was available. The new system began 1, 1949.

ospital organisation was divided into departments e regarded as cost centres. These fall naturally am groups:

"Patient" departments concerned directly with patients and contributing to diagnosis and treatment.

For each department a unit of production was chosen (table 1). For service departments the unit is one which bears relation to the services given to other departments and which can serve as the basis of the allocation of their cost to patient departments. For patient departments the unit is one which will best enable the cost of various treatments to be compared, and which will allow the cost of a patient or of a patient day to be calculated showing the different components of the cost, such as the maintenance cost of a patient and the cost of the special treatments and diagnostic services used by the patient.

The estimate of the first standard cost per unit was reached in the following way:

An estimate was made of departmental expenditure for the year based on information for the past adjusted to cover known changes in the future. This was the first standard cost.

An estimate was then made of the number of units which each department would produce during the year, based on information for the past of total possible production adjusted if necessary to the number which it was thought would be required from the department. This was the first standard number of units.

A simple division of the standard number of units into the standard cost gave the first standard cost per unit.

These first standards were of course far from reliable, but a start had to be made somewhere. At the end of the

first year the standard was revised in the light of the information then available and of a more precise definition of departmental expenditure and activity.

Expense is allocated to departments as it is incurred. This arises from three main sources—direct cost of materials, direct cost of labour, and indirect cost.

Direct cost of materials consists of materials purchased especially for the department, materials issued from stores, and, in patient departments, drugs issued from the dispensary and the cost of patients' food. Each source is separately accounted for so that variances in cost may be easily seen and traced to their cause. Materials issued from stores are grouped under the same headings as the supplies officer uses for the stores' records. Materials are priced out to departments at a standard price, and any variance appearing on the departmental statement thus arises from differences in consumption, and the effect of price variation is only shown for the hospital as a whole.

Direct cost of labour is arrived at by an analysis of the hospital pay roll. Variation will occur through changes in hours worked and in rates of pay.

Indirect cost consists solely of those items of expenses attributable to the buildings as a whole and is spread over departments on an agreed basis.

A periodical statement is prepared for each department comparing the actual cost of its running with the estimated standard cost (table II). A summary of these departmental statements shows the position for the hospital as a whole. If it is thought necessary to arrive at the total cost of any patient department, a further statement is prepared showing the allocation of the cost of service departments to the patient department.

DISCUSSION

I have given no details of the method employed in this particular hospital in arriving at the costs, for the idea of working on a standard basis was grafted on to an existing system originally designed for other purposes. But the experiment is an attempt to provide information for the use of the administration and for purposes of comparison. When similar experiments have been carried out in other hospitals or groups of hospitals it will be possible to arrive at some idea of the best methods to be employed, of the cost of costing, and of the best use which can be made of the results.

But it seems clear that a system based on these principles has the following advantages.

It affords a scientific basis for annual estimates. It gives an automatic control over budgets, consumption, and stock, more especially as the original estimate is varied according to changes in the services produced.

By basing departmental analysis on a standard shows the result of variation in price of materials change in price levels or in buying policy.

It enables each departmental head to be aware of in such expenditure as he is able to control.

It provides a basis for comparison of hospital cost national or regional level by a comparison between standard cost of departmental units of production in hospitals and between the number of units produced.

It would in the course of time enable a standard cost ascertained for all hospital departments from standard cost could be built up for individual according to the departments they contained. This would provide a method of control of expenditure at national levels.

When cost information is available for a number of and for a period of years, it should give a useful of the best size of departments and hospitals, and of the efficient methods of providing various services, and it enable estimates to be made of the cost of the provision of additional services. Variation in the standard cost of departments in individual hospitals should show the effect of bed-occupation and of varying methods of administration.

The statistics automatically collected for arriving at costs can be used for other purposes. They can, show to what extent the special departments are used different types of patient.

Now that financial control is vested in hospital management committees dealing with a group of hospitals, unit of administration is big enough for the system to be properly planned and organised. Such a unit the analysis of expenditure under mental headings, rather than the headings of at present required, should not entail any great labour, especially as some mechanisation would be possible. The collection of the other data the calculation of the standard cost could be made part of the accounting system, and could be obtained from patient records without alteration or addition. But it is important, the fullest use is to be made of any costing information should always be up to date. It may be available as soon as possible after the end of financial period, and each period should not be too long. To introduce costing, however, will not by ensure efficient administration. Costing is not a cure for inefficiency, though it is as essential to good management as the use of X-ray and other diagnostic instruments are to a good doctor. But the results must be presented in a useful and intelligible form to the administrator who must be willing to accept and use this new effective weapon.

EDICAL SERVICE FOR AUSTRALIA

AN AUSTRALIAN CORRESPONDENT

In a lost year in the last twenty that did not abortive solution to the economic problems practice in Australia. But it now seems that soundly based is coming to fruition.

One put forward by Sir Earle Page, F.R.C.S., Minister of health, is based on a combination of aid with nation wide voluntary insurance against sickness and disease. This partnership is a plan that both State and individual have obligation in national health scheme, and it will use all means and organisations that have been built up in the restoration of health. The option leaves everyone free—the doctor, the hospital management and staff, the chemist, voluntary or insurance organisation. An Australian scheme has been based on the principles:

It must be within the financial compass of the State and the nation and able to be controlled by the State.

The plan should contain within itself automatic checks and controls on costs, on abuse of the time and skill of the doctor, on the waste of expensive medicine and diagnostic tests, and on the inefficient and uneconomical use of hospital beds.

There must be no interference with the personal relation between doctor and patient.

The patient should be given a definite sense of personal responsibility.

The willing co-operation of doctors, chemists, hospital management, voluntary organisations, insurance societies, should be secured by leaving in their expert hands as much of the administration and control of the scheme as possible.

The existing agencies and methods that have proved so effective in the past should be used to the greatest possible advantage.

It must be an element of permanence in the plan to development and extension of the machinery that will deal with confidence new problems.

The effect of the scheme must be to raise the level and standard of medical care and treatment, and not to degrade the standard of medical care and treatment, and not to undermine it, to stimulate progress in the art of healing and encourage continuous research.

Attempts have been made in different countries to give free medical treatment or to give free treatment to the patient's expense. These over simplified solutions have proved wasteful in their administration, disastrous to the quality of treatment, and destructive of the morale of the people. Effective control was impossible without co-operation of the medical profession has been lacking, and governments have been unable to budget adequately for their financial commitments or to limit them. If the quality of treatment declines, health must suffer, and this must occur also if the system that previously spurred doctors to give devoted service is being destroyed.

The challenge therefore is thrown out to Australia to meet the challenge of a very modern society as to how advantage can be taken of our great advances in knowledge and the methods kept within the means of the people. If Australian ingenuity and intelligence can satisfactorily answer this challenge, the best minds of the community will be devoted to the healing art and the future of medicine will be assured.

The criterion of success of a national health scheme is a decrease in the sickness rate of the community.

The sign of failure is that more medicine is used and more treatment becomes necessary. Sir George Murray is confident that voluntary insurance, with State aid to deal with special classes and to meet deficiencies in the period and extent of the assistance due to the actuarial limitations of the

insurance available on the premium charged, will solve the problem. There will be free choice of doctor and no interference with the doctor patient relationship. Plans and organisation will be the result of co-operation between the consumers and providers of the medical service. There will be a minimum of governmental interference and control, and a definite incentive to improved standards.

For generations, voluntary insurance has been the standard method of dealing with risks. Voluntary insurance involves a minimum of interference with the traditional life and activity of the community. Voluntary insurance has been invaluable against all unpredictable risks such as sudden death, shipwreck, theft, and fire. Should not voluntary insurance against unpredictable risks of disease prove just as valuable as in these well tried cases?

In Australia there are over 5 million life assurance policies with annual premium payments of over £35 million, giving voluntary insurance cover for over £1000 million. Accident and sickness insurance companies cover hundreds of thousands more people. Friendly societies insure over 600,000 families against sickness and medical treatment amongst other risks. The various hospital insurance funds insure well over half a million. There are many medical and hospital benefit insurance organisations associated with trade unions covering at least another half a million families.

STARTING THE NEW SERVICE

The new scheme is to be implemented in two stages, and there are four phases to the first stage.

Improvement of nutrition by the provision of milk daily to all children under the age of 12 years. Distribution of the milk will be arranged in co-operation with State governments and will relieve them of the responsibility for the cost of this service.

Prevention of disease by a national health educational campaign and by the free provision, on a doctor's prescription, of costly, specific life saving and disease preventing drugs, and of drugs necessary for certain chronic illnesses. Abuse will be checked by professional disciplinary committees composed of representatives of the medical and pharmaceutical professions.

Curative measures for serious disease by contributions towards hospital costs and maintenance, through subsidised hospital insurance schemes, provided in such a way as to restore to hospital managements the control of hospital administration. This contribution will both relieve patients' expenses and substantially assist hospital finance.

The relief of the high cost of medical treatment by combined voluntary insurance and governmental benefit up to 90% of the cost of medical treatment. Abuse of these benefits will be checked and controlled by the patient still paying part of the doctor's fee and by the supervision of voluntary organisations which disburse the benefit. These organisations will provide from their own funds an amount at least as much as that provided by the government. Advisory committees of doctors, chemists, and voluntary organisations will be formed also to supervise this benefit.

Special provision will be made for medical service to the indigent and to old-age, invalid, and widow pensioners, the temporary unemployed, and other selected classes.

The second more comprehensive stage of the scheme will deal with the capital cost needed to place the national health machinery in an efficient and up to date condition, and can only be tackled after exhaustive discussions with State governments, universities, medical schools, managements of teaching hospitals and of regional, base, and country hospitals, and with other bodies associated with the care of the sick, with nutrition, and with health.

Both stages will be designed to ensure a progressive improvement in all phases of medicine—from teaching and research through to actual practice and the training of medical graduates. Both stages will aim at restoring

the position, prestige, and fullest usefulness of the general practitioner. The proposed administration will avoid the creation of any large numbers of new public servants.

A list of free drugs, drawn up by a specialist committee of the British Medical Association, is to come into operation on Aug. 14. The list includes the sulphonamides, insulin, streptomycin, penicillin, vaccines, intravenous protein hydrolysates, and other solutions and new expensive drugs not yet in general use.

The doctor uses his own prescription form or a government form as he chooses. The prescription is given in duplicate. When handed to the chemist, these prescriptions are made up without charge to the patient. The chemist will receive from the government the fee for the prescription according to an agreed schedule. It is estimated that this part of the plan will cover 2% of the prescriptions at present compounded. In serious illness 70% of the cost of drugs would be met. The cost of this part of the scheme is estimated at £2½ million a year.

The pensioner group, who with their dependants number about 1 million, will receive an enlarged service of free medicine to cover their more common ailments. Apart from this group, there would be no means test in the operation of the scheme.

Insurance schemes cost 6d. per week for single persons without dependants, and 1s. per week for a man, wife, and dependants under the age of 17. With the government subsidy, this payment would cover 90% of medical costs.

A public opinion poll shows that 46% of the public think that all medicines should be free, 34% only want the expensive drugs supplied, 11% think none should be free, and 9% have no opinion.

Public Health

Poliomyelitis

In England and Wales notifications in the week ended Aug. 5 were: paralytic 262 (197), non-paralytic 105 (108), total 367 (305). Figures for the previous week are shown in parentheses.

The following county areas, with notifications as given, contributed some 69% of the total notifications in the week under review.

	Paralytic	Non-paralytic
London	16	12
Essex	14	3
Gloucester	6	5
Lancaster	15	7
Middlesex	8	3
Northumberland	8	6
Southampton	8	3
Stafford	21	12
Surrey	10	2
Warwick	24	14
Worcester	21	5
Yorks (West Riding)	18	6

The total increase for the week of 62 compared with the previous week was due to larger numbers of notifications in a number of counties, of which the more important were Hertford, Kent, Lancaster, Lincoln (Holland, Kesteven, and Lindsey); Northumberland, Stafford, Surrey, Worcester, Yorkshire (West Riding). Notifications of non-paralytic cases dropped to 20% of the total compared with 35.4% in the preceding week.

Cases notified in the Isle of Wight in the week ended Aug. 5 were: paralytic 4, non-paralytic 3, and numbers have since increased to a total of 28 confirmed cases including 26 paralytic, reached on Aug. 12. The medical officer of health has advised that visitors with children should not visit Freshwater and Newport for the time being. This advice does not apply to the rest of the island. Up to Aug. 13, there had been no notifications from the main coastal resorts on the Isle of Wight.

In England Now

A Running Commentary by Peripatetic

THERE are times when I can only conclude that hospital administration was built up without for the patients. "How smoothly our department would run," one can imagine a strator saying to his junior, "if there sick people all over the place." At times seems that they—the mysterious "they"—hospital—go on strike and refuse to admit patients.

My patient must have been caught in such. Her nose had been destroyed by lupus and at teaching hospital a pedicle graft was taken to as a preliminary to repairing the damage. Next 2 years she wrote and telephoned saying the pedicle was well and strong and ready moved to higher places. Seven times the replies of increasing terseness from "them" to would be notified when a bed was ready.

She was a humble and placid soul and finally accept the fact that her pedicle was destined on her arm. It is twenty years since she last reply.

"Would you like it done now?" I asked she replied "I have got used to my nose pedicle is useful for tucking my hankie in."

THE COMMITTEE MAN OR

FROM WHITBY TO WHITLEY

1 I've travelled to London by sleeper I've travelled London by plane
In Winter it's freezing in Summer it's hot
Springtime it's raining in Autumn it's no
I've tried all the trains and I hate all the lot,
10.25 to the 1 o'clock Scot
I'm fed-up, I'm finished I feel that I ought
quietly at home but I'm off like a shot,
And I travel all over again.

2 Agenda are written on yellow, agenda are white,
And, would you believe it, agenda on pink.
What a queer use of paper—a queer use of ink!
Just to gather our facts, just to coax us to
Just to bind us together—to strengthen a link
Between Counties and Countries—to lead us to
Our Committee is dazzled, but knows itself!

3 We marched to the Ministry in Whitehall
Tavistock Square we passed—
The Surgeons, the Physicians,
The newborn Obstetricians,
Housed our arguing Chiropractors,
Seeking tactical positions,
For their "Terms and Conditions,"
Keep step—Eyes right—Stand fast.

4 But now a faint nostalgia dalls our senses
There's lingering love for days not long ago.
What boys we were! Consultants' best defeat
Were us—or so we thought—none saying
Oh Whitley Council's come to Town, come
come to Town,
Whitley Council's come to Town, come to
stay.

(If the reader has strength he now reads verse)

The annual sports day at my daughter's school highlight of the local summer season. Mother their housewifely cares and kitchen aprons, and hours parade in all their glamour, furtively other mothers and making sibilant comments friends on the subject of suitable dress for the. The mothers are ensconced in deck-chairs on side of the sports field, while fathers lurk under the trees in the background, perspiring.

Letters to the Editor

FIRE

SIR,—Your annotation on fire and burning accidents prompts me to send you some stop press news. The Registrar General's report for 1948 shows that the deaths from burns and scalds have again dropped—from 1266 in 1938 to 838 in 1947, and now to the record low figure of 620 in 1948. In terms of the population at risk that means a drop of from 30 per million in 1938 to 14 per million in 1948 (The corresponding figure for the United States was still 31.5 per million in 1947). The falling death rate in this country should not, however, be taken as ground for complacency. If, as I suspect, it means rather the recovery of a larger proportion of severely burned people than a reduction of the total accidents, the prevention of these burns is still a matter of great importance—because the severely burned people who recover represent a formidable occupancy of hospital beds, and many of them recover as sub efficient, unhappy people.

The Registrar General's report brings out another striking fact for the second year running the most common cause of fatal accidents by burning was not contact with an open fire but with an electric fire. In other words, these fires have now become "the outstanding hazard of the English home", 59 deaths are ascribed to them in 1948 as compared with 46 to coal fires and 30 to gas fires. And it must be remembered that the non fatal burns from each of these causes amount to about 10 times these figures.

The effective guarding of electric fires becomes, then, a matter of urgency. But, as your annotation points out, the protection of the public against this menace is still not in sight. The long drawn out deliberations (they have lasted more than 3½ years) of the committee of the British Standards Institution have not yet produced any agreed specifications of safety for electric and gas fires. Indeed the situation is worse than that: the committee has reached a deadlock, because the makers of gas fires will not agree with makers of electric fires. So we are back where we were in 1947, when the committee was set up, and in the interval, something like 150–200 people have lost their lives—and about 10 times as many have been seriously injured—by contact with unguarded gas and electric fires. I submit that if the representatives of the manufacturers of these fires (and the BSI committee is largely composed of them) had displayed real concern to stop the supply of these dangerous fires to the public, specifications of safety could have been drawn up within 6 months—perhaps within 3 months. Even if agreement should, some day, be reached by makers of fires upon the specifications of safety there is still no guarantee that all makers will conform to those specifications. They are not required by law to do so.

Is it not time that the task of defining the specifications of safety should be assigned to an independent body of technical experts whose findings the makers of fires would be required by the Government to accept? Why should England be the last country to protect its children and old people against this very obvious hazard in the home?

There is one more item. The fireproofing of inflammable cotton clothing materials seems now to be somewhat nearer. I have recently tested some unbleached calico and a finely woven patterned cotton print treated by the 'Erifon' process (salts of antimony and titanium) introduced recently by Messrs DuPont in America.

The untreated material flamed fiercely as soon as it touched the candle flame used for the tests, and was reduced to a fine meshwork of ash within 15 sec. The treated material, in contact with the candle flame or the element of an electric fire for 3 sec, did not burst into flame: it developed a line

(in vain) that they will not be called on for race

is in the 10–12 year group, and being a long for her age, won a sprint race and was second a jump. Flushed with my success—I should mention that my group of fathers was betting 3 win, 3d place—I determined to risk all my on the last event of the day, the brothers and e Young Peter is only three, and I managed ne good odds. Sure enough, in the first heat ped him firmly by the hand and won in a canter, ink Peter's feet touched the ground more than he 30 yard course.

e, in the front row of the stalls, was beaming when the finalists lined up at the starting gate, ood to win at least 5s if my pair came home or mistress raised her pistol, and then— y I want my POTTIL!" Every mother along instinctively alerted, but I knew Peter's voice as there first. I pleaded with the mistress to e the start. I argued, I cajoled, I told her of my i habits, but all to no avail. The race must. Sadly my daughter returned to her mother, eter and I wended our way, the exposure of all the schoolroom toilet, sadly I rejoined my friends he trees. I suggested that all bets were void, as an had not come under starter's orders, but I was led. Is there any other owner trainer whose entry an scratched for incontinence?

it a grease smear on a suit soon after we got to ca. The dry cleaners failed to remove it by routine or. Rather than risk more heroic measures, I ed a simple Anglo-Saxon could save his dollars olve the problem with a little petrol, so I plunged e of rag into my Austin's tank on the end of a piece e and pulled. The wire came back with my hand, o my horror, the rag stayed behind ar people tried to get it out last week. I fished ar wire, the "gas station" men drained the tank probed about with various gadgets, friends joined un from time to time but got hot and irritable trying move the tank, shining torches down the spout, so on. All was in vain, the rag remained in situ, nance to the fuel system. The family drivers were ed of the risks of a sudden blockage of the petrol—no close overtaking in traffic to show off the per nance of the British car, and no long cross country , until the rag was out. Meanwhile, new plans were

When no-one was about to give advice we bought ne-cent fish hook, attached it by a thread to the cap, and washed it down with a few gallons of gas returned home computing the chances of a catch as jumped over the roads.

unwily enough, we forgot (? suppressed) all about this for several days—indeed, until an hour ago. Then lled on the thread, and there was a distinct resistance tly, slowly, with coaxing and prayers, the thread e on, and out came the rag, red-dyed! The gas ion men had gone home when I got there to tell them, I had to share my triumph with someone v wife got the spot off my suit several days ago with e turpentine she found. Women are so practical, men, men are inspired.

* * *

ow that the Channel swimming season has once more ed I will reveal two plans of my own. I am training tadpole, Ena, to make her attempt towards the end e month. I anticipate that the Adaptation Syndrome apply here, and I shall therefore give Ena 'Cortisone' ng her 'exhaustion phase'. What this will do to the animal I cannot imagine, but I shall be content if does not metamorphose before reaching Dover. I also organising a mass swim by the two thousand ents and three hundred and forty staff of my hospital gard this as a Pilot Scheme which will doubtless be ed by others on a larger scale. The occupational apy department has completed the training pro me, and when the Great Day arrives I hope to have whole hospital breast-stroking off Bournemouth un ten minutes of the start. The order of precedence still to be settled: the MS will lead us, but does s or the SHMO bring up the rear?

of "glow" at the point of contact with the source of the heat. This glow slowly extended (it did not break into flame even if fanned) and extinguished itself within 20-40 sec. Only a small portion of cloth was destroyed by the glow.

Precisely the same result was obtained with samples of treated fabric soaked overnight in (1) tap water, (2) rain water, (3) soap and tap water, (4) soap and rain water, (5) then—in each case—washed in the normal way, and (6) boiled twice, for 30 min. each time, both in tap and rain water.

Clearly the flame resistance—however it is achieved—is remarkably "fast." And I am informed by independent observers in America that the materials have shown no deterioration or loss of flame resistance after exposure out of doors for several months to hot sun and weather. The colours of the printed fabric I have seen are not quite so bright as those of the untreated sample, its feel is not appreciably harsher. I am informed that patch tests (for toxicity) were made on about 190 people in the DuPont laboratory (though no actual tests have been made of toxicity for children), and that "ingestion tests were made on animals."

The new process seems to carry us some way towards safer clothing, though it does not appear to give 100% flame resistance since the proofed material will burn if it is doubled over the elements of an electric fire (thus presenting a larger surface to the heat). The process does undoubtedly confer a considerable margin of safety, however, and I think one may assume that 3 times out of 4 a frock or nightdress made of such proofed material would not burst into flame from a momentary contact with a fire (as our present cotton and viscose rayon clothing will do), and that if a glowing point was established by such contact the glow would easily be put out.

It is not yet certain whether the new process can be applied equally well to the cheap raised cotton fabrics, such as flannelette and winceyette, which are so extensively used by the lower wage earning classes, in whose homes most of the burning accidents occur. Moreover, the economic problem of producing these cheaper proofed fabrics at competitive prices has yet to be overcome. But it must be remembered that we already have to pay a very high price for the care of so many seriously burned people. The new process certainly seems worthy of the attention of the Department of Scientific and Industrial Research.

Farnham Royal, Bucks.

LEONARD COLEBROOK

THE SCHOOL MEDICAL SERVICE

SIR,—Prof Alan Moncreiff's Dawson Williams lecture¹ on the reorganisation of the infant welfare clinics and school medical services was most timely, and with regard to the former it contained excellent suggestions. The school medical service, on the other hand, could and to some extent does meet a real need.

The intensive propaganda for health of the pre school child, immunisation, food and vitamin supplements—in fact all the mechanical aids which could be supplied, joined with the parent's interest—helped to produce our present healthy babies. Nothing could be more profitable than for the infant welfare clinics now to turn their interest to other technically preventable diseases.

There has not been any comparable activity for positive health in the school child, nor can the remedy lie in anything as easily administered as foods or injections. Yet the importance of the first ten years of life cannot be surpassed by any later impressions, and no one could deny that the latter half of these growing years produces in many homes difficulties the effect of which may be more lasting than the benefits of the earlier age.

The school medical inspection is the only reminder to parents that an interest is still in the child, and most of them welcome it. Attendance there completes the chain of ground, school, and health. The contact with all children with problems—the enuretics, the asthmatics, the undernourished, the ailments clinic, where time is available and an hastener anxious to help.

The child whose main illness is his parent who frets and broods but cannot help herself in a crowded surgery, though she feels the problem does not warrant hospital treatment, those (some 40% of hospital outpatients) or management difficulties have already a situation weighty enough to require special and investigation. All these and more find to the school clinic at some time during those years.

That is why these school clinics could be used as the real centres of preventive medicine, in the nation for healthy adulthood. The composite provided by the health visitor, by the teacher's by the history, and by the parents' attitude, is or most complete at present available to any doctor competes for pride of place with the family knowledge of the background and character. The final aim of any National Health Service produce a healthy nation. The seed is sown years, and in these days of successful treatment major ailments we ought not to neglect to deal with many, common, troublesome symptoms, which grow large enough to eat up all the fruits of our efforts.

It would require but an acknowledgment of the of these school medical services—and some reduction of red tape—to make them a lively, discriminating of the other medical services, to relieve the practitioners, to act as a clearing house for outpatients, and to be of inestimable value to population at large in giving a helping hand to problems are in their infancy.

By relegating school doctors to plan syllabuses meals and to be concerned with postural defects only should be wasting something the full use of which greatly need.

Gidea Park, Essex.

HEDY SYMONDS

Assistant School Medical Officer

SIR,—I did not have the pleasure of listening to Professor Moncreiff's lecture, one would like to know what experience he has of school medical inspection, what knowledge he has of its potentialities. The statement used by Dr Gordon, and quoted in your annotation that "the injudicious doctor may implant a neurosis by unnecessarily emphasising some harmless or minor condition" is merely a reflection on the doctor and not on the principle of school medical inspections. Any doctor is capable, either consciously or unconsciously, of implanting neuroses in his patients would be well advised to give up the practice of medicine.

The School Medical Service makes no claim to curative service, it should be entirely preventive in outlook and application. The value of personal individual discussion with the mother on the aspects of health and the prevention of disease, as our present knowledge will allow us to go, is the best forms of health education. The school inspection affords an excellent opportunity to this instruction. To expect the already overburdened general practitioner to carry out this aspect of health education and preventive medicine is almost bordering on the ridiculous.

Launceston Cornwall

L. RICHARDS

¹ Delivered before the section of child health of the British Medical Association and briefly reported in *The Lancet* Aug 5 1950 p 222 with comment on p 218.

DRUGS IN PARKINSONISM

In reference to your leading article of June 17, in connection with 'Diparcol', 'Benadril', 'Artane', 'Lysivane', and we have carried out a controlled observation comparing artane and diparcol with drug 'Lysivane'.

There is no hesitation in commending the use of artane in parkinsonism. It is much less toxic than Lysivane, has a somewhat wider range of effectiveness than artane, and apparently its effects are more than those of paripamit. The effect on patients is remarkable. We have a series of patients who have been bedridden and unable to attend to the requirements of hygiene who are now walking and looking after themselves. Lysivane, therefore, in common, takes pride of place among the drugs up to date. Occasionally it can be combined with benadril with benefit to the patient, and there are occasional cases which respond better to artane than to Lysivane.

One of the most interesting aspects of this form of parkinsonism is its extraordinary effect on the patient's motor effects, but we do not feel that this is a satisfactory total explanation. The sense of "being out of the spot," which is perhaps the most significant symptom of parkinsonism, invades the mental aspects of the patient as well as the motor, and we often find that our patients treated with Lysivane "loosen up" in their mental life in a manner which does not seem to be satisfactorily explained simply in terms of the disappearance of rigidity and tremor.

HAROLD PALMER

c Hospital, Dunedin N.Z. D. J. A. GALLAGHER

CHLORAMPHENICOL IN WHOOPING-COUGH

In view of the antibiotic action of chloramphenicol on *Haemophilus pertussis* in vitro and its protective effect in infected animals, as well as encouraging clinical results, a large scale clinical trial has been carried out.

In 25 early cases of whooping-cough were given the drug. Of these, 9 were in the catarrhal stage, 11 were just at the start of the paroxysmal stage (2-5 days), and 5 were rather at the beginning of the paroxysmal stage (5-10 days). All were contacts of well-developed whooping-cough. Of the 25, 20 had, or later developed, a characteristic spasmodic cough sometimes associated with whooping. In the other 5, the spasmodic cough did not develop. The diagnosis was confirmed by leucocytosis with relative lymphocytosis (over the blood sedimentation rate was normal, and the Mantoux fixation test became positive later in the disease). All patients had no spasmodic cough for about one month (over the maximum incubation period) during which they were in intimate contact with cases of whooping-cough and did not develop it.

In the 9 patients in the catarrhal stage, 2 ceased to cough in four days, and another 3 continued to cough an insignificant cold like cough for 1-2 weeks. In the 11 patients in the paroxysmal stage, 7 had, despite the drug, a quite typical, though less severe, spasmodic cough which continued for 4-6 days, after which they had a mild bronchitis like cough for 1-2 weeks. The 9th case was least affected by the treatment. The patient developed a rather severe spasmodic cough which continued for seventeen days. This patient happened to have severe diarrhoea for over a week at the start of the treatment, and this might account for the apparent

lack of effect. In 16 patients in the earlier part of the paroxysmal stage (2-5 days) 15 were much relieved by the fourth day. The improvement affected the frequency, duration, and severity of the paroxysms. The whole paroxysmal stage lasted 9-17 days and the patients then had a mild cold like cough for another 1-2 weeks. The 16th

patient, however, showed from the fourth day a remarkable improvement in the severity and frequency of the paroxysms, and whooping ceased, but a rather severe spasmodic cough continued for over three weeks. This patient was receiving a heavy dosage—80 mg per kg body weight in the twenty four hours for a short period (five days only).

Different dosage schedules were tried, and we feel that the best is 50 mg per kg body-weight as an initial dose, divided into four portions given over forty five minutes, followed by 50 mg per kg body weight in the twenty four hours, divided into six-hourly doses. This dosage is continued for a week—that is, till the paroxysms are mild and broken up, and thereafter half this dosage is given for a further 7-10 days. The drug was given in a gum emulsion syrup, and provided it was taken on an empty stomach vomiting seemed to cause little trouble.

The mild course and short duration—or the complete absence—of the paroxysmal stage in 23 of the 25 cases tested can hardly be ascribed to chance. In this series chloramphenicol, given early, has transformed an intractable and lengthy disease into a mild and almost insignificant ailment. The details of our work will be published later.

EX-PATIENTS AS TUBERCULOSIS NURSES

SIR,—I would like to suggest that priority in admission to sanatoria should be given to those who are willing to undertake, when cured, to work as assistant nurses for a fixed period before returning to their normal occupations. I imagine that a patient who has spent several months in bed acquires a useful familiarity with the simpler aspects of nursing. In this way the patient would be encouraged to acknowledge his debt to society, and by repaying it would help to relieve the present shortage of sanatorium nurses. This proposal to select patients on other than purely medical grounds may conflict with medical tradition, but its adoption would, I submit, shorten the waiting lists for admission.

TRANSVESICAL PROSTATECTOMY

SIR,—I was most interested to read the article by Mr Crawford Stanley in your issue of Aug 5 describing his technique of transvesical prostatectomy, as I have been using a practically identical one in suitable cases of benign prostatic enlargement since May, 1946, and have now carried out this procedure on 79 patients. I developed the operation as a modification of that described by Cannady in America about fifteen years ago, modifying it so as to achieve a one-stage technique, and was not aware that it was being performed elsewhere in this country.

I also can bear witness to the excellent results obtained, which parallel those described by Mr Stanley. The period of convalescence and the end results appear to be equally satisfactory to those obtained after the Millin procedure, whilst there is no doubt that it is very much simpler technically besides permitting the performance of any other associated intravesical operation.

The youngest patient on whom the operation has been performed was 43 years of age and the oldest 84, the average age being 67.9. The average length of stay in hospital after operation has been just over 12 days in uncomplicated cases, and the patients appear to obtain complete urinary control—even at night—within the following 3 months. Clot retention has been unknown, undoubtedly owing to the closure of the bladder over the prostatic cavity. I have not been quite so unfortunate as Mr Stanley over the development of subsequent

epididymo orchitis, which has only occurred in just over 10% of cases, but I believe that this is probably due to the "tidal drainage" employed whilst the catheter is in position. I believe that this complication is inevitably due to secondary infection during healing of the prostatic bed, and I attempt to control this by using continuous irrigation with 1 in 10,000 oxytetracycline solution. Only one case has developed post prostatectomy obstruction, and this was in a patient with secondary proteus infection which took a long time to subside.

I agree with Mr Stanley that this operation has a definite place in prostatic surgery and that its success, in all modern one stage procedures, is dependent upon the principles of closed bladder drainage and prevention of urinary infection.

Leicester

A DAVIS BEATTIE

ACQUIRED IDIOSYNCRASY TO SODIUM p-AMINOSALICYLATE

SIR,—In his interesting article of Aug 5, Dr James Cuthbert points out that published reports on severe toxic reactions to P.A.S. are scanty. His is the first I have seen in which a positive skin reaction has been obtained to a patch test done with sodium P.A.S. One case has been reported in which a reaction to a patch test with aspirin was positive but that to P.A.S. was negative.¹

The opportunity of investigating this phenomenon recently presented itself in the case of a woman, aged 25, in my wards in West Middlesex Hospital who developed pyrexia and an erythematous rash eighteen days after starting on a course of 1 g streptomycin and 18 g P.A.S. daily. The rash disappeared after stopping both drugs but recurred eleven days later when a single dose of sodium P.A.S. was given by mistake. Patch tests to various strengths from 5% upwards of sodium P.A.S. showed a strongly positive reaction, and, in view of this, chemically pure sodium P.A.S., meta aminophenol, and sodium salicylate were procured and tests repeated with these drugs. No reaction was obtained to control patches or to patches containing 20% salicylic acid or 20% streptomycin, but strongly positive reactions were obtained to 20% P.A.S. and to solutions of meta aminophenol ranging from 1 to 20%.

This patient was later desensitised with gradually increasing doses of sodium P.A.S. given under cover of 'Phenergan,' and it is interesting to note that the fading patch tests became itchy as soon as the dose was increased too rapidly. When the patient was able to take 18 g daily the patch tests to 20% sodium P.A.S. and meta aminophenol were repeated. The former proved to be negative but the latter still produced a

C = Control S.S. = Sodium salicylate P.A.S. = Sodium P.A.S.
M.A. = Meta-aminophenol The figures indicate percentage strength of the patches

distinct reaction. Control tests on other had been given sodium P.A.S. proved negative. It would seem, therefore, that in severe cases the sensitising agent is much more likely derivative of meta aminophenol than salicylic.

Ealing

HUGH J.
Physician to the

SIR,—It was most interesting to read Dr Cuthbert's case record, for a reaction occurred in one of which was also characterised by symptoms of cold, prostration, pyrexia, glandular enlargement, and a rash.

The patient was a man, aged 50, who suffered a bilateral apical tuberculous infiltration which responded well to rest treatment. P.A.S. 14 g commenced on April 11, 1950, but by April 21 he was of having a cold in the head, and in the evening temperature rose to 100.2°F. The sensation of having a cold was followed by marked malaise and aching pains in the arms and shoulders. By April 29 his temperature reached 101.4°F and the lymph nodes in both posterior triangles of the neck were slightly enlarged and tender. On May 3 a fine rash appeared on the chest, abdomen, and forearms. Temperature, which had continued to rise in the evening, reached 103.2°F. P.A.S. was discontinued and the temperature fell by the next day, and remained normal thereafter. The rash cleared in twenty-four hours, and the general malaise together with the enlargement of the cervical lymph nodes subsided within the week following the discontinuation of P.A.S. therapy. No albuminuria was noted during the reaction, and the Widal test was negative for group and *Brucella abortus*.

On May 14, 14 g of P.A.S. was given, and during the night the patient again felt that he had a head cold and complained of general malaise. The temperature rose to 98.4°F on the morning of May 15, and thereafter at a slightly higher average level than during the previous week. On May 17 the feeling of malaise became more pronounced and aching pains were present in the legs, and the temperature reached 99.4°F. P.A.S. was again discontinued, and by the next day all symptoms had disappeared. A scratch test done with a drop of P.A.S. on the skin gave no reaction. As in Cuthbert's patient, no vomiting or diarrhoea occurred and this man did have some nausea at the onset of his reaction.

No other patient taking the same stock solution of P.A.S. developed a reaction. Davin and Rogers¹ reported 4 cases out of 85 in which a febrile reaction occurred, the temperature rising to 103–104°F and subsiding promptly on withdrawing P.A.S.

Aborigine Sanatorium

J. B. MORRISON
Medical Superintendent

SIR,—The case reported by Dr Cuthbert has removed our last remaining doubts about the cause of a syndrome which affected a patient in this sanatorium.

Three weeks after admission, the patient, a single man, aged 23, started on a course of sodium P.A.S., 20 g daily. His condition remained satisfactory until the 26th day of the course, when his temperature rose to 100°F and continued to rise, reaching 104.6°F 2 days later (pulse 132 per min). His only symptom was headache, which was unaccompanied by any other abnormal signs. The P.A.S. was discontinued, a total of 560 g having been given, but the temperature did not immediately return to normal as is usually the case in idiosyncrasy to this drug. Another 2 days, without any change in his condition, followed. A conjunctival oedema was noted, and he complained for the first time of nausea and anorexia. Simultaneously a macular rash appeared over the 'bathing drawers' area, spreading in the course of the following week to cover the whole body and cause much distress through a severe pruritus. Jaundice deepened rapidly and persisted for 3 weeks before beginning to fade. The liver was never greatly enlarged, and although palpable for a few days was not very tender. The spleen was never palpated. The temperature returned to normal by lysis between the 10th and 15th day of the illness. The patient's general condition continued to deteriorate till repeated vomiting. Intravenous saline drip was given.

¹ Davin J. R., Rogers A. E. T. *Amer. Rev. Tuberc.* 1947, 61, 1.

developed oliguria and a raised blood urea a very distressing symptom. The rash began on 19th day and was followed by desquamation of all layers of skin. On the 24th day the blood 8 mg per 100 ml following complete anuria for he patient was comatose and his legs oedematous after his condition began gradually to improve, finally made a complete recovery.

Wassermann and Kahn tests were negative and is excluded by agglutination reactions, and raised by the Casoni test. Homologous serum as considered because blood had been taken for sedimentation rate estimations before admission. These did not fit in with the length of the period of this disease. Epidemic infective was regarded as improbable but could not be excluded. The blood showed a polymorphoecytosis (24 000 per c mm) and an eosinophilia of is suggested a toxic hepatitis with an allergic basis supported by the presence of the rash. Owing to extremely severe illness we did not feel justified in any sort of sensitivity test, but no drug other than had been taken up to the time when jaundice and there now seems little doubt that this was the antihistaminic was given for a few days, but did not seem to alter the course of the illness. The allergic nature of the is not realised in the early stages when anti-histamine might have been of service—we have in fact found that with milder skin reactions due to P.A.S. sensitivity is usually effective. Once the jaundice appeared we suggest that the stage of allergy had been passed and the cells had suffered some irreversible damage. The had no previous history of allergy.

Blood P.A.S. levels were estimated at weekly intervals the time the patient was taking the drug, the figures 11 mg, 6.7 mg, 12 mg, and 11.4 mg per 100 ml, the figure being for the first day of the illness. Although figures are above the average for patients taking this of P.A.S., we have had many patients with even blood levels who have not had any sort of toxic reaction.

P.A.S. is now probably the most widely used drug treatment of tuberculosis, it is important that such a dangerous form of toxicity should be recognised in its apparent rarity.

E W STREFT

Sanatorium Kent

DIMERCAPROL IN LEAD POISONING

In your issue of July 29 (p. 171) Dr Bastrup describes two cases of acute lead poisoning treated with dimercaprol (BAL), which showed an increased excretion of lead in the urine during treatment.

One cannot subscribe to the conclusions which draw—that "Dimercaprol must be regarded as a real and effective means of increasing the excretion of lead in acute lead poisoning."

In the first place the lead-BAL complex, unlike those of mercury and arsenic, is not non-toxic but, according to Gurnuth and Eagle¹ is twice as toxic as lead.

In the second place BAL does not produce any appreciable deleading. For example, in mice I have found that, when lead was administered in the food for 10 days, subsequent treatment with dimercaprol had no effect on the final lead content of the animals and his collaborators² while reporting a transient effect on the urinary excretion of lead in men treated with BAL, state that they have been unable consistently to alter the clinical course of lead intoxication or to obtain a significantly increased rate of elimination of lead by giving repeated doses of BAL.

On the present evidence—and there is much more

than I can give in this letter—there appears to be no indication for the use of dimercaprol in lead poisoning.

School of London W 12

G M BULL
BERNARD LEVON

TOBACCO AND LUNG CANCER

SIR.—One might add the petrol lighter to your list of possible causes of the suspected increase of cancer of the lung (p. 257 last week). Judging by advertisements in the *Illustrated London News* and other journals, the cigarette lighter became popular about the time of the 1914-18 war—a chronological coincidence sufficiently close to be suggestive.

There is some comfort in the thought I find it easier to use matches than to give up smoking.

Ipswich

R M MAYON WHITE

Obituary

HENRY CUTHBERT BAZETT

C B E M C, M A, D M OXFORD, D SC WEST ONTARIO, F R C S

NEWS of the death of Dr Bazett on July 12 on his way to England to attend the meeting of the Physiological Society at Oxford came as a shock to many who attended the meeting. Two colleagues, one from each side of the Atlantic, who feel that "something more is needed than recitals of degrees positions held, and honours to mark the passing of such a man" have sent us the following tributes.

* * *

Two outstanding characteristics impressed themselves on the graduate students scientific collaborators and university colleagues who knew and respected Bazett as man and scientist. The first was a dominating, generous enthusiasm. Bazett, when telling of, or listening to, an account of experiments that gave a glimpse of new scientific truth or suggested new ideas in physiology was like a small boy given a bicycle. Age did nothing to diminish this ebullition of enthusiasm, and it was unspoiled by any worldly taint of personal ambition or the jealousy that so easily besets even the scientist. I have so often seen Bazett at federation meetings, not hobnobbing with the important people but spending his time in discussion with some young student who had, he felt, done honest work and had ideas that should be encouraged. The same enthusiasm made him a great teacher of the medical undergraduate, though his lectures were apt to be complicated in detail and perhaps sometimes too advanced for their immediate comprehension. Every student felt that, after all, physiology must be really important and exciting if this man was so enthused. How often Bazett must have been late home to dinner because he had lost all sense of time explaining patiently to some student the answer to a question which had revealed a genuine interest and intelligence. Surely the essence of great teaching is this power to infect the student with enthusiasm, rather than the highly organised lucidity that is so much admired.

Another of H C B's enthusiasms was swimming (and of late years painting). No matter how cold the water or how unattractive, to the rest of us, the opportunity, he was impelled to dive into any pool, stream, or

ocean available. He belonged to a club near his home where there was a deep cylindrical tank converted to a pool. Dr Bazett would challenge all to dive to the greatest depth, and I never knew him outshone by his much younger rivals. Again, in the undergraduate teaching laboratory, Dr Bazett would compete with students in breath holding experiments, and seldom if ever be beaten. To see him urging on a student in a voluntary hyperpnoea was never to be forgotten. He made physical recreation an opportunity for acute physiological observation, and physiological observation was to him a recreation.

The same enthusiasm of Dr Bazett included, as well as physiology, all things connected with the welfare of science in general. He was a leader in any movement to safeguard the liberties of scientists, and after the war organised help to fellow scientists in Europe and Asia by sending them journals, reprints, and apparatus. And though he served the country of his adoption so well, he always leapt to the service of Britain and the Commonwealth. In 1940, when the United States was not yet at the war, he begged leave of absence from the University of Pennsylvania to come and take part in aviation medical research then starting in Canada. The growing claims of his responsibilities in the United States made him return, but when six months later the death of Sir Frederick Banting left the Canadian civilian research effort in this field without a leader, Dr Bazett hastened to our aid once more and took over direction. This was at a considerable financial and personal sacrifice. Later in the war he served the whole Allied war effort by journeys, including those to India and Burma, for consultation and research with the R A F and the R N.

A second outstanding characteristic of the man was his great moral and physical courage. This is attested not only by his record in the first world war, but by the many heroic and even dangerous experiments in human physiology in which he loved to be the pioneer. He was always himself the first subject of an experiment and often performed operations upon himself of which few of us would be capable. As he grew older, this was a source of considerable worry to his friends, but he could not be dissuaded when he felt that fundamental scientific information could be gained no other way. When he was engaged in the early investigations of the effect of G, he would visit various R C A F stations and ask in the mess who was the best and most daring of stunt pilots. Then he would persuade this man to take him up and see how soon he could make him black-out. So alarmed did Dr Bazett's friends in administrative posts become, that confidential orders were sent to the stations that this man was not to fly in such stunts, as he was too valuable to lose in such a way. I do not know whether he ever discovered this, if so he would have been infuriated. I have been in many an altitude chamber experiment with him in the early days of the war. He would suffer the acute and very painful type of aerobolism, his colleague nothing but mild rheumatic distress. Yet it was Dr Bazett always who insisted on going up again after a few minutes of descent. It may well be that he gave part of his life span for science by the type of heroic physiological experiments he made.

The memory that so many will carry of Dr Bazett from seeing him in discussion at meetings will be that of a delightful kind of pugnacity. He was like a terrier after a rat, when he was on the trail of scientific truth. Again, to continue the simile, he never ceased to attack the bone of a fact until he had cracked it open and extracted the marrow of truth. And he had the rare gift of criticism without giving offence, but rather encouragement. He was generous with his advice, interest, and time. To hundreds of us he must have been a great friend as well as a great physiologist. We will not soon forget him. The impress of his life upon us was deep, and many of us will model our researches on his teaching, and our conduct upon his.

A C B

Bazett was this year elected president of the American Physiological Society, a remarkable honour for a man who retained his British citizenship, but an arduous post, especially for a man of his enthusiasm and vitality. The outstanding work carried out in his department at Philadelphia was accomplished with the minimum of elaborate equipment. In spite of the austerity of his

laboratory, there was always an eager graduates working there, inspired by his subject, and delighted by his endearing and sense of humour.

His contributions to physiology were his greatest interest was in temperature, the control of the circulation. The main work was carried out on human subjects, employed in most experiments was H C was once suggested to him that he should with the title *The Physiology of H C Bazett* an astonishing disregard for himself in his but they were never undertaken in any of self-sacrifice. He had such a curiosity he just had to find out, and if the involved considerable discomfort for himself, that matter? His experiments were beautiful human physiology is singularly full of pitfall unwary, but Bazett showed that exact work on man as well as, if not better than, work on dog.

It is not surprising that his services were demanded during the war. His work in Canada, Banting Institute and then in the United effort was outstanding, and once more the ability to work with a team of investigators produce work of fundamental importance with ad-hoc problems.

After the war, Bazett and his colleagues more exact techniques for studying the temperature in circulating blood. They showed importance of venae comites in the control of temperature, arterial blood in the limbs, it is by a venous plexus can be pre-cooled by the venous blood, so a temperature gradient can length of the limbs. This has proved a fruitful in explaining some of the peculiarities of the in the limbs and has also helped to explain paradoxical changes in rectal temperature.

His loss is a sad one for his colleagues in Canada, and in Britain, and he will be particularly at Copenhagen, where he was expected at the International Congress on Physiology. Those who worked same field will miss his advice, which was widely and freely given. His papers and contributions books and symposia will continue to be many years.

Dr Bazett, who had held the chair of physiology University of Pennsylvania since 1921, was born the son of Dr Henry Bazett of Gravesend, educated at Dover College, Wadham College and St Thomas's Hospital. He qualified in after holding house appointments and a demership in physiology at St Thomas's he was Radcliffe travelling fellowship in 1912 which enabled him to spend a postgraduate year at Harvard. He returned to this country shortly before the war, during which he served with the R A M C. For his services he received the M.C. and was mentioned in despatches and on his demobilisation was also appointed O.B.E. From 1919 till up his appointment in Philadelphia. Dr Bazett was also appointed lecturer in clinical physiology at Oxford. He was appointed C.B.E. in 1946 research work in the late war.

In 1917 Dr Bazett married Miss Dorothy L. survives him with a son and a daughter.

GEORGE RAPHAEL BUICK PURCE

M.C., M.C.H. BELF. F.R.C.S.E.

THE eldest son of the late James Purce of Baco Antrim. Mr G. R. B. Purce was educated at the Academic Institution and Queen's University, where he had a brilliant career, qualifying with honours in 1914. During the 1914-18 war he served with the 8th battalion of the Royal Irish Rifles, and he was awarded the Military Cross. After he was demobilised he took the M.C.H. in 1920 and the F.R.C.S.E. the following year. He quickly won recognition as a surgeon and was appointed to the staff of the Royal Victoria Hospital, Belfast. The Ulster Volunteer Force Hospital, the Ulster Hospital for Children and Women. He was

surgeon to the Forster Green Hospital and er Sanatorium. He was consulting surgeon to er hospitals in the province
 } writes "Purce's surgical career is a story t pioneer work not only in thoracic surgery, him in 1948 to the presidency of the Association ic Surgeons of Great Britain and Ireland, but urosurgery in which for many years he did the re of the work in Ulster. All this was in addition idest range of general surgery and involved a f work which only a man of his exceptional powers could have achieved. Despite this he to maintain the keenest interest in a wide subjects and was always increasing his already wledge. From playing hockey for Ireland as man his interest in sport was maintained all He was a first-class shot with either rifle or , and a keen golfer and fisherman, and when his in navigation was stimulated by a yacht-holiday, it was typical of him that he was not till he had mastered the mathematics and l details of this anything but simple subject. a teacher his great store of knowledge and l experience was available for the asking to all those e enough to work with him but his own distaste form of parade or showmanship prevented him eading much valuable knowledge as widely as ould have wished. He was too busy doing his o be talking about it unasked and when in dis- of surgical problems his advice was sought he d himself simply and helpfully to the point where en might have been drawn into a demonstration r knowledge. His surgical skill and judgment ed almost uncanny, but he was never one to : in spot diagnosis, and his decisions, though wifly made were the logical and carefully weighed of his great experience. In operating no con- cious of surgical difficulty or personal fatigue were llowed to cloud the main issue of what was the procedure for the patient's ultimate welfare and) this completely selfless attitude to his work that u owe their lives and health. His position as a u can never be in dispute but it is even more great qualities as a man and a friend that Barney will always be remembered by those who knew rked with him."

ERNEST THOMAS JENSEN M.B. LOND

Ernest Jensen who died in London on July 31 age of 76, will be best remembered for his work uman of the Institute for the Scientific Study of quency. But his posts and activities were many ualified from Guy's Hospital in 1901, and in his days he was a civil surgeon to the Herbert Hospital, rich. He also served with the field force in the war, and later he joined an expedition into unknown of British East Africa. A fellow of the Royal v of Tropical Medicine and Hygiene he was the er of the Tropical Disease Prevention Association. e was also an original member of the Society for the of Radiesthesia.
 Grace Pailthorpe writes "In 1931 when I was is to start an association for the scientific treatment nquency, Dr Jensen became a co-founder with me it is now known as the LSTD and he was its an from its inception until his death. He gave usly in time and money towards the institute, r years he housed it in his home until in 1937, financially strong enough to move to its own in Portman Street. This period was shortlived m in the late war the house was bombed. Once Dr Jensen came to the rescue and he spent himself ngly until he had found a new home for the) at 8 Bourdon Place, Mayfair.
 During the war he often attended to street casualties. one occasion he himself received slight wounds iving splinters. Dr Jensen was much beloved patients, medical colleagues and friends. His and his power to give of his time without stint, less of his own gain, endeared him to all who knew. He was of that old régime that, regrettably, has most ceased to exist. His lived to serve."

MARGARET RANKEN M.B. DURH

Dr Margaret Ranken of Sunderland and Newcastle, died on Aug 7 after a short illness.
 Miss Ranken qualified M.B. from the University of Durham in 1924 and after various resident appointments specialised in ophthalmology as her life's work. She had been associated with the eye department of the Royal Victoria Infirmary, Newcastle upon Tyne, for almost twenty-five years as house-surgeon, refractionist, registrar and associate surgeon. Since its inception Miss Ranken had been surgeon-in-charge of the orthoptic department at Sunderland Eye Infirmary, which is the orthoptic teaching school of the region, turning out a steady flow of qualified orthoptists. In 1943 she was appointed ophthalmic surgeon to Durham County Hospital where she was in charge of the eye department until 1946 when she was appointed ophthalmic surgeon to the Ingham Infirmary, South Shields.
 J. S. A. writes "Miss Ranken's great interest was in the treatment of squints, on which she was a recognised authority, and she elected to operate while the patient was still very young. Her success in this field of ophthalmology was due to her surgical skill, her unlimited patience, and her fondness for children with whom she was able to develop an extraordinary degree of confidence and friendship. Miss Ranken had an entirely altruistic outlook on life, and if she could do a good turn to anyone she did so without counting the cost to herself. She was concerned with the benefits which she in her profession could convey to humanity rather than in any personal gain.
 "Among her general interests, Miss Ranken was a member of the Central Orthoptic Board, an active member of the Medical Women's Federation, and past-president of the Sunderland branch of the Soroptomists, of which she was secretary for many years. By Miss Ranken's death the community has lost a modest and well-loved doctor, and the profession a skilful and dependable ophthalmic surgeon and a colleague who will be difficult to replace."

MEDICAL SYMPATHECTOMY" IN HYPERTENSION

NICAL STUDY OF METHONIUM COMPOUNDS

RICHARD TURNER

O.B.E., M.A., M.D. Camb. F.R.C.P.

SICIAN, WESTERN GENERAL HOSPITAL, EDINBURGH
LECTURER IN MEDICINE UNIVERSITY OF EDINBURGH

HE the hexamethonium and pentamethonium compounds block the transmission of nerve impulses through autonomic ganglia, their potential range of action is wide. This preliminary paper is concerned with their possible use in essential hypertension in order to produce effects comparable to those of surgical sympathectomy. No attempt can yet be made to assess the results of treatment, but as others may be considering a trial of these compounds it was suggested that it is an account of the experience gained during the past months would be of interest.

Sympathectomy is an unscientific method of dealing with hypertension: one cannot even foretell whether it will lower the blood-pressure at all or for a reasonable period. Admittedly medical sympathectomy is equally unscientific, but it is a gentler procedure and would be valuable if equally effective. Whether it is always able to reduce the pressure in patients with marked hypertension is a separate question. A high pressure is a symptom but one manifestation of hypertensive disease, not necessarily the most important. But so long as pathogenesis remains unknown, all treatment must be empirical, and at present it is mainly directed at reducing the pressure.

One of the anaesthetists who first used pentamethonium and hexamethonium compounds to counter the effects of local anaesthetics, the lowering of blood-pressure which they produced was a troublesome or even a dangerous side-effect. But this action was of natural interest to physicians.

THE COMPOUNDS AND THEIR ACTION

Strictly speaking the term "medical sympathectomy" does not correctly describe the action of pentamethonium and hexamethonium, which is not confined to one part of the autonomic nervous system. But for practical purposes this is their main effect.

Their chemical and pharmacological properties have been described by Paton and Zarnis (1948a and b, 1949), and by Ing (1948a and b) and Balaban et al. (1949). Day and Smith (1950) found hexamethonium iodide (H.M.I.) an effective and innocuous means of reducing gastric secretion and motility in patients with peptic ulceration, and it may prove a useful means of treatment. Little effect on the blood pressure was observed in patients with normal tension.

Arnold and Rosenheim (1949) investigated the effect of hexamethonium iodide (H.M.I.) in normal and hypertensive patients. They gave it by intravenous, or sometimes intramuscular injection and demonstrated that the vasodilator action was similar to that of tetraethylammonium (T.E.A.) but stronger and of longer duration. They concluded that postural hypotension was likely to limit its value in treatment and that its most promising application was to peripheral vascular disease. Later with Goetz they reported its peripheral vasodilator action (Arnold et al. 1949).

Turner and Graham (1950) made detailed studies on the effect of H.M.I. and P.M.I. on the blood pressure, peripheral circulation, and sweating in normal, vasospastic and hypertensive subjects and likewise concluded that postural hypotension was likely to limit their employment.

Then penta- (or hexa-) methonium iodide (or bromide) given by intravenous injection to hypertensive patients, the blood pressure usually falls precipitately. This action is almost immediate but short-lived. Hence the value of these compounds is of little value, except as evidence that the blood pressure is in fact high. 100 mg is usually well

tolerated without appreciable side effects, but 50 mg will serve to demonstrate whether the preparation is effective in the particular person. A typical response is shown in fig 1 and compared with an injection of tetraethylammonium bromide (T.E.A.B.) in the same patient.

On intramuscular injection of the compounds the fall in systolic and diastolic pressures begins within fifteen minutes, and is usually as great as that produced by an intravenous injection, but the pressure thereafter rises more slowly, and (with the patient recumbent) the previous level is not reached for three or four hours or longer. This being the customary effect, we soon found that intravenous injections could be dispensed with altogether. The next step was to try to maintain the blood pressure at a reasonable level throughout the day. (There is no need to maintain a continuous state of response to these drugs throughout the 24 hours, for it can be demonstrated that a blood pressure which is labile and

Fig 1—Comparison of effect of T.E.A.B. (400 mg) and pentamethonium bromide (50 mg) given intravenously to the same patient (lying).

to give in the first place. The injections should be spaced so that the next is given just as the pressure begins to rise again.

Having ascertained the effect of regular injections with the patient in bed, a similar trial should be made with him up and about. Under the influence of these drugs, the blood-pressure is much affected by posture, and injections must at first be given with the patient under close observation for fear of excessive hypotension. There is little risk of a faint when walking about: the danger is in standing still. For example, a patient was quite all right when walking from hospital to the bus-stop, but trouble came when he was standing in the queue. Symptoms related to postural hypotension can largely be obviated by wearing an abdominal belt or binder, as is done after surgical sympathectomy, and patients should be advised to contract the abdominal muscles at the earliest indication of faintness, or if possible to lie down. This particular difficulty can usually be overcome in practice.

Assuming that a permanent state of lowered pressure produced by these preparations is desirable for hypertensive patients, the next question was whether regular doses by mouth during the day would produce this result without undesirable side-effects. An average dose to begin with was 1 g in solution three times a day, and if this proved insufficient the amount was gradually increased. It became clear that in cases where the blood pressure could be lowered by giving the drug by injection it could also be lowered by giving a larger dose by mouth. In most patients with hypertension this has been found possible, but it is not at all easy to establish a fixed daily dose for any particular person. Even when the drug is given by injection its action seems to vary and sometimes to be cumulative. Postural hypotension likewise varies and consequently it is

difficult to maintain a fairly steady level for anyone leading a reasonably active life, even when wearing an abdominal belt or binder. When these drugs are given, the pressure varies widely with rest and relaxation, walking, sitting, standing, and emotion. Perhaps because of varying absorption or metabolism, the variation is greater when the drug is taken by mouth. Though these difficulties may be overcome by perseverance they indicate the need for special care in administration to outpatients.

ASSESSING THE EFFECT

The assessment of drugs like this is not at all easy. First, it is essential to establish the normal levels of blood pressure throughout the day, both lying and standing. In hypertensive patients especially, the level varies considerably from hour to hour and day to day, and this means that any lowering of pressure must be considerable and consistent before significance is attached to it. Naturally pressures must be taken with the same technique, and they should be taken on the same arm. If possible they should be taken by the same person. The pressure usually settles a good deal in the first few days after admission to hospital, and it is best to complete the other investigations, such as electrocardiography, radiography, and estimation of renal function, before attempting to ascertain the basal levels. Also one must try to determine which symptoms are really related to the hypertension. Symptomatic relief is by no means a reliable guide to prognosis: objective evidence is better.

ILLUSTRATIVE CASE HISTORIES

Some of the difficulties are evident from the following case histories.

Case 1—Mr A, aged 46, was a stable married man referred because of headaches, dizziness, and increasing shortness of breath on exertion over the past two years. Casual B.P. readings were usually about 230/240/130-150. There had been no suggestion of ischaemic pain. General condition good though rather overweight. No signs of cardiac failure. Normal rhythm. Apex beat not displaced but somewhat heaving. No triple rhythm but wide splitting of the first heart sound at the apex (confirmed by phonocardiography). Accentuation of aortic second sound. No murmurs. Lungs clear. Fundi showed no papilloedema, haemorrhages, or exudates, but there were grade II hypertensive changes in the retinal vessels (Wagner and Keith 1939, Keith et al 1939). Screening showed some hypertrophy of the left ventricle but no pulmonary congestion. E.C.G.s (14 leads) were compatible with moderate left ventricular hypertrophy but revealed no evidence of infarction. Renal function slight impairment. Other systems normal.

The hypertension was shown to be labile. Casual readings fell somewhat with rest and relaxation in hospital to 220/110. The B.P. fell with amylobarbitone narcosis to 150/100 and with T.E.A.B. (0.5 g intravenously) to 130/70. Following 40 mg of pentamethonium iodide (P.M.I.) intravenously, it fell to 115/70. The effect of a single intramuscular injection of H.M.B. is shown in fig 2: the diastolic pressure remained under

Fig 2 (Case 1)—Effect of a single intramuscular injection of hexamethonium bromide (lying).

100 for about six hours. The effect of two injections of hexamethonium bromide (H.M.B.) is shown in fig 3 and that of three injections of hexamethonium bromide (H.M.B.) in fig 4. Similar results were obtained on other days. Side reactions varied widely. Sometimes he felt rather weak and sick during the day and at other times there were no unpleasant effects.

Observations were made with varying postures—i.e., lying flat with the foot end of

Fig 3 (Case 1)—Effect of two intramuscular injections of methonium bromide in the day (lying).

the bed raised on blocks, and then with the head end (about 18 in). These manoeuvres had little effect on the (Subsequent observations showed that raising or lowering of the bed is insufficient for assessing the effect of posture, the patient should sit up or, if necessary, stand.)

It was apparent that two to three intramuscular injections a day would maintain a B.P. more or less within the normal range and without undue side-effects. A dose of 60 mg by mouth produced no appreciable fall in pressure, and was little effect from a further 1 g taken three hours later. Next day 2 g was taken as an initial dose, but five hours later the pressure was still 200/120. Consequently a further 5 g was given. This may have been somewhat premature and over generous, at all events there was a good fall in pressure which was 140/90 after three hours and remained about this level until he went to bed at 10 p.m. He complained of feeling squeamish and rather faint when he took a bath after tea, and his standing pressure at this time was found to be 95/65. On waking next morning it was 145/90, and throughout the day he felt nauseated and was troubled by diarrhoea. On the following morning this had passed and he felt well again. On other occasions with smaller

Fig 4 (Case 1)—Effect of three intramuscular injections of hexamethonium bromide in the day (lying).

better spaced dosage (e.g., 1.5 g t.d.s.) comparable results were obtained. However, he never really felt well in himself on this régime, though quite free from his previous symptoms. No matter how much care is taken to avoid introspection, frequent estimations of the B.P. may produce anxiety in hypertensive patients. During the period of observation he became free from symptoms but it was felt that continued attempts at "medical sympathectomy" were unwarranted, and surgical sympathectomy was advised and accepted. There was an unfortunate sequel in that he died from pulmonary embolism.

Case 2—Mrs B, aged 51, was a woman of worrying disposition in whom hypertension had been discovered three years previously. She had been troubled with headaches for years and after a particularly bad spell, accompanied by sparks and lights flashing in her right eye, she awoke one morning to find her left eye completely blind. Six months later she had another period of severe headaches and considerable epistaxis. Light months after this she had a sharp right-sided paroxysmal headache accompanied by flashes in front of the eye. These features persisted and reminded her of the events on the previous occasion so that she feared losing the sight of this eye too. It was for this reason that she sought advice.

Thus but general condition good. Casual B.P. readings 200-240/110-120. No signs of cardiac failure, normal rhythm and pulse wave. No clinical enlargement of heart. Normal sounds and no murmurs. Fundi showed

atrophy, right disc normal, grade 1 hypertensive changes only. Urine trace of albumin, no cells. Iates but definite evidence of impaired renal function. um specific gravity 1016 blood urea 50 mg per l, urea-clearance 25% of average normal function. enous pyelograms normal. Screening of the heart i no general enlargement slight rounding of the entricles, slight unfolding of aortic arch, no hilar stion. ECGs showed slight changes compatible with ntricular hypertrophy.

h amylbarbitone narcosis the B.P. fell from 240/120 0/90 and with T.E.A.B. (400 mg intravenously) to 00. After 50 mg of H.M.B. intramuscularly the pressure fell to 105/90 two hours later, and in another three hours 00. She was then complaining of abdominal pain and found to have considerable distension. Various other i were tried and it was found that normal pressures l be maintained by two to three injections a day, each l, 75, or 100 mg. single dose of 2 g of P.M.B. resulted in a relatively normal ure throughout the day (fig 5), but a feeling of giddi-

5 (Case 2)—Effect of pentamethonium bromide by mouth (standing)

by the abdominal distension it caused, which was not erved by adrenaline. Apart from this, she felt very well.

This case illustrates how difficult it is to evaluate the ion of these drugs with any precision. Though an r all lower level may be maintained, there tend to greater variations in pressure than in hypertensive ients not under treatment and such lability may harmful.

Case 3—Mr C, aged 68 had always been exceptionally ergetic until ten years previously when he began to notice ue tiredness. He consulted his doctor who found a high ., kept him off work for two months, and put him on a diet .eafter he remained well until three months previously en he noticed momentary weakness and dizziness on mbing stairs. After a short holiday he felt much better an. Two weeks before admission to hospital he was iting on the blackboard in his class at school when he idenly developed a headache, felt very queer for a few onds, and found he could neither write nor speak. He nt outside for a drink of water and recovered completely thin ten minutes. His doctor prescribed phenobarbitone week later he had a similar experience lasting a few minutes

6a (Case 2)—Effect of pentamethonium bromide by mouth (standing)

Fig 6b (Case 2)—Effect of pentamethonium bromide by mouth (standing) on another occasion

ular fibrillation, pulse of high tension. Apex beat not palpable, split first sound in mitral area. accentuation of aortic second sound. no added sounds or murmurs. Casual B.P. readings 260/160 after rest in bed 240/130. Fundi: no papilloedema. haemorrhages, or exudates. grade 1 hyper-tensive arterial changes. Lungs clear. Other systems normal. Screening: moderate enlargement of left ventricle, aorta uncoiled and dense, no hilar congestion. ECGs normal apart from auricular fibrillation. Urine: no albumin, casts, or cells. Specific gravity concentration test 1022. Blood urea 30 mg per 100 ml.

With amylbarbitone narcosis the B.P. fell to 135/95 and with T.E.A.B. to 150/85. Preliminary studies with H.M.B. by intravenous and intramuscular injections established that the B.P. was labile and could be maintained approximately within the normal range by repeated doses. Side-effects were inconstant: on one occasion he had vomiting and loose motions, on another he fainted in the bathroom. (Though the possibility had been discussed, adequate advice about postural hypotension had not been given.) 0.5 g H.M.B. and later 1 g given by mouth had little effect. 1 g t.d.s. resulted in an average pressure of 160-180/110-120 between 10 A.M. and 7 P.M. with a further fall to 150-160/100 in the evening. When 1 g t.d.s. was given for three consecutive days the average pressures were 175-190/120. On 1.5 g t.d.s. they were 170-180/100-115 during the day with a fall to about 150/90 in the evening. With 2 g t.d.s. the average readings were 160-170/100-110 in the day and 135/100 in the evening at which time he felt faint. These findings suggested a slight cumulative effect throughout each day.

On one occasion he was given 5 g by mouth as a single dose when his resting pressure was 220/130. Six hours later, shortly after the pressure was found to be 140/105 (recumbent) he was sitting in a chair listening to the wireless when he suddenly found he could not speak, owing to weakness of the left arm he could not take off his dressing gown. This reminded him of his previous attacks during teaching at school. He recovered within ten minutes and did not send for a nurse or doctor. When the house physician arrived half an hour later he was quite well, his B.P. was 180/130 lying and 100/80 standing. Next day he had a slight headache and a tingling sensation in the left arm and leg. He was troubled with diarrhoea and vomiting which was attributed to the H.M.B. but the attack was presumably of hypertensive origin, of a similar nature to those he had previously experienced and unconnected with the fact that he was taking a hypotensive drug.

Various other combinations were tried in an endeavour to find a satisfactory daily régime and again some degree of tolerance was apparent. He lost all symptoms related to his hypertension and was troubled only by these occasional reactions and a vague feeling of malaise when under treatment. He was getting anxious about his B.P. and on the whole did not seem to be deriving much benefit. Accordingly he was allowed home and at his urgent request back to work. During the five months since then he has remained symptomatically well, though the general level of his B.P. is unchanged.

The wisdom of attempting to lower the blood pressure in a case like this is discussed below.

EFFECT ON VENOUS PRESSURE

Observations were made on a woman with severe hypertensive congestive failure who had never been

After this he was troubled with intermittent head aches but otherwise felt well. No breathlessness or other relevant symptoms.

General condition good but overweight. Plethoric appearance. No signs of cardiac failure. Auri-

difficult to maintain a fairly steady level for anyone leading a reasonably active life, even when wearing an abdominal belt or binder. When these drugs are given, the pressure varies widely with rest and relaxation, walking, sitting, standing, and emotion. Perhaps because of varying absorption or metabolism, the variation is greater when the drug is taken by mouth. Though these difficulties may be overcome by perseverance, they indicate the need for special care in administration to outpatients.

ASSESSING THE EFFECT

The assessment of drugs like this is not at all easy. First, it is essential to establish the normal levels of blood pressure throughout the day, both lying and standing. In hypertensive patients especially, the level varies considerably from hour to hour and day to day, and this means that any lowering of pressure must be considerable and consistent before significance is attached to it. Naturally pressures must be taken with the same technique, and they should be taken on the same arm. If possible they should be taken by the same person. The pressure usually settles a good deal in the first few days after admission to hospital, and it is best to complete the other investigations, such as electrocardiography, radiography, and estimation of renal function, before attempting to ascertain the basal levels. Also one must try to determine which symptoms are really related to the hypertension. Symptomatic relief is by no means a reliable guide to prognosis; objective evidence is better.

ILLUSTRATIVE CASE HISTORIES

Some of the difficulties are evident from the following case histories.

Case 1—Mr. A, aged 46, was a stable married man referred because of headaches, dizziness, and increasing shortness of breath on exertion over the past two years. Casual B.P. readings were usually about 230/240/130-150. There had been no suggestion of ischaemic pain. General condition good though rather overweight. No signs of cardiac failure. Normal rhythm. Apex beat not displaced but somewhat heaving. No triple rhythm but wide splitting of the first heart sound at the apex (confirmed by phonocardiography). Accentuation of aortic second sound. No murmurs. Lungs clear. Fundi showed no papilloedema, haemorrhages, or exudates, but there were grade II hypertensive changes in the retinal vessels (Wagner and Keith 1939, Keith et al 1939). Screening showed some hypertrophy of the left ventricle but no pulmonary congestion. E.C.G.s (14 leads) were compatible with moderate left ventricular hypertrophy but revealed no evidence of infarction. Renal function slight impairment. Other systems normal.

The hypertension was shown to be labile. Casual readings fell somewhat with rest and relaxation in hospital to 220/110. The B.P. fell with amylorbarbitone narcosis to 150/100 and with TEAB (0.5 g intravenously) to 130/70. Following 40 mg of pentamethonium iodide (P.M.I.) intravenously, it fell to 115/70. The effect of a single intramuscular injection of H.M.B. is shown in fig 2: the diastolic pressure remained under

Fig 2 (Case 1)—Effect of a single intramuscular injection of hexamethonium bromide (lying).

100 for about six hours. The effect of two injections of hexamethonium bromide (H.M.B.) is shown in fig 3 and that of three injections of hexamethonium bromide (H.M.B.) in fig 4. Similar results were obtained on other days. Side reactions varied widely. Sometimes he felt rather weak and sick during the day and at other times there were no unpleasant effects.

Observations were made with varying postures—i.e. lying flat with the foot end of

Fig 3 (Case 1)—Effect of two intramuscular injections of methonium bromide in the day (lying).

the bed raised on blocks, and then with the head end (about 18 in.). These manoeuvres had little effect on the (Subsequent observations showed that raising or lowering of the bed is insufficient for assessing the effect of posture; the patient should sit up or, if necessary, stand.)

It was apparent that two to three intramuscular a day would maintain a B.P. more or less within the range and without undue side-effects. A dose of 0.5 g by mouth produced no appreciable fall in pressure and was little effect from a further 1 g taken three hours later. Next day 2 g was taken as an initial dose, but five hours later the pressure was still 200/120. Consequently a further 5 g was given. This may have been somewhat premature and over generous, at all events there was a good fall of pressure which was 140/90 after three hours and remained about this level until he went to bed at 10 P.M. He complained of feeling squeamish and rather faint when he took a bath after tea, and his standing pressure at this time was found to be 95/65. On waking next morning it was 145/90, and throughout the day he felt nauseated and was troubled by diarrhoea. On the following morning this had passed and he felt well again. On other occasions with smaller and better spaced dosage (e.g. 1.5 g t.d.s.) comparable results were obtained. However, he never really felt well in himself on this régime, though quite free from his previous symptoms.

No matter how much care is taken to avoid introspection, frequent estimations of the B.P. may produce

anxiety in hypertensive patients. During the period of observation he became free from symptoms, but it was felt that continued attempts at 'medical sympathectomy' were unwarranted and surgical sympathectomy was advised and accepted. There was an unfortunate sequel in that he died from pulmonary embolism.

Case 2—Mrs. B, aged 51, was a woman of worrying disposition in whom hypertension had been discovered three years previously. She had been troubled with headaches for many years and after a particularly bad spell, accompanied by sparks and lights flashing in her right eye, she awoke one morning to find her left eye completely blind. Six months later she had another period of severe headaches and considerable opistaxis. Eight months after this she had a sharp, right-sided, paroxysmal headache accompanied by flashes in front of the eye. These features persisted and reminded her of the events on the previous occasion, so that she feared losing the sight of this eye too. It was for this reason that she sought advice.

Thin but general condition good. Casual B.P. readings 200-240/110-120. No signs of cardiac failure. Rhythm and pulse wave normal. No clinical enlargement of heart. Normal sounds and no murmurs. Fundi showed

Fig 4 (Case 1)—Effect of three intramuscular injections of hexamethonium bromide in the day (lying).

made to mask the difficulties. In fact, emphasis is placed on them deliberately lest it should be that a new era in treatment has come. There are so very many patients in whom symptoms due to hypertension cannot be relieved by other means. Undoubtedly, however, there are some, these, especially when the hypertension is severe, symptoms disabling, methonium compounds are of trial. They usually relieve symptoms so far this relief is due to the drug and how far concomitant rest and relative freedom from stress or domestic affairs is not always easy to determine. Perhaps in such cases it would be best to discard sphygmomanometer and try to find a dose of pentamethonium bromide which will relieve symptoms without any unpleasant side-effects. Patient and practitioner then may be able to decide.

In the long run, perhaps, the scientific approach is important.

hemodynamics

essential hypertension, at least until advanced stages are reached, cardiac output is unaltered, and surgical sympathectomy there is no material change, whether or not the blood pressure is lowered (Lums et al 1941, Smith et al 1946, Wilkins et al 1949). It must mean that the total peripheral blood-flow is unchanged by operation and that any local increase in flow must be compensated for elsewhere. In adjustments of flow throughout the body must be in balance.

In hypertensive patients, sympathectomy causes significant changes in blood flow through the kidney (Moran and Page 1941, Selzer and Friedman 1941, Liley et al 1942, Foa et al 1943, Talbot et al 1943). When the arterial pressure has been lowered by operation, it is possible that renal flow may be maintained by local vascular adjustments in the kidney resulting in decreased resistance. Alternatively the fall of general arterial pressure might be due to such decreased resistance. These problems are not yet solved. It has been reported from Stockholm that glomerular filtration renal blood-flow, and the excretion of urine are reduced by an injection of T.E.A.B. in normal persons (Aas and Blegen 1949). If this is true of patients with hypertension, the methonium compounds may well have a similar reverse effect.

Cerebral blood-flow has been shown to be normal in uncomplicated cases of hypertension (Kety and Schmidt 1948, Schenberg 1950). The relief of headaches by sympathectomy has been attributed to restriction of cerebral blood flow (Fishberg 1948). Certainly vasomotor constriction occurs in the upper limbs after this operation. Despite more than ten years' study, the hemodynamic effects of surgical sympathectomy are not yet thoroughly understood, nor are the reasons for success or failure known. When a fall of arterial pressure does occur it is not even certain that this can be directly explained by dilatation of the splanchnic bed (Wilkins et al 1949). In patients under treatment with methonium compounds the blood-pressure falls considerably. Observations on cardiac output and blood-flow through various organs will therefore be of great interest. Such studies would certainly be made before there is any general tendency to treat patients with hypertension with these drugs.

Actions and Side effects

With "medical sympathectomy" produced by the action of a drug which paralyzes the transmission of nerve impulses through sympathetic and parasympathetic ganglia, the effects on the body may be widespread. Actually, with the doses employed to lower the blood-pressure to a satisfactory level, there is usually little

obvious effect on other parts of the body such as the bladder or bowel. Some patients have gastro-intestinal upsets in the form of constipation, looseness or distension. Some complain of a vague feeling of general malaise, and others of dryness of the mouth and slight mistiness of vision.

Postural hypotension is the chief problem, and alarming collapse has been reported twice in patients under investigation elsewhere.

Assessments should therefore always be made in an institution in the first place, so that over-reactors will be discovered. During this period adrenaline should always be at hand.

Fig 7—Effect of sitting up after intramuscular doses of pentamethonium bromide.

Effect of Posture

It must not be assumed that because with the patient recumbent, an injection causes little apparent effect on the blood pressure, the drug is not having any action.

Fig 7 shows the results of observations in one case. 50 mg P.M.B. was injected intravenously with the patient lying on her bed with no apparent effect. Accordingly a further 50 mg was given, again with little effect. Slight fluctuations in the resting B.P. may be related to the natural reactions to repeated B.P. recordings and the manipulations needed for the injections together with the activities of an ophthalmologist who was endeavouring to study the effects on the retinal vessels. She

Fig 8—Effect of posture eight hours after 5 g of pentamethonium bromide by mouth.

was then asked to sit up, whereupon the pressure fell promptly. On lying down again it gradually rose to the previous levels.

Another patient who was up and about was given a single dose of 5 g P.M.B. by mouth and the pressures were recorded at intervals throughout the day after lying down (Fig 8). Twice during the evening the pressure was recorded before she lay down, and as can be seen from the figure considerable postural hypotension was still evident.

Tolerance and Intolerance

It is difficult to be sure about the development of increased tolerance to the drugs, but the evidence suggests that it may occur in some degree. No instance of idiosyncrasy has been observed.

Choice of Preparation

As regards investigation and treatment, we have found little difference between the four preparations used—the iodides and bromides of pentamethonium and hexamethonium. Pentamethonium bromide, which

treated with rest, digitals, mercurial diuretics, or even sedatives

A continuous intravenous heparin drip attached to a water manometer was used to record venous pressure. Arterial pressures were taken at short intervals on the other arm with an ordinary sphygmomanometer. After a preliminary period of observation P.M.B. was injected into the venous drip. The arterial and venous pressures fell to normal levels simultaneously, and were maintained there over a period of two hours by occasional injections of P.M.B. through the rubber tubing. Screening examination had shown considerable pulmonary congestion and probably oedema.

As a simple clinical experiment it was then decided to see whether a continuous state of lowered venous pressure induced by P.V.B. would result in a diuresis and hence prove of benefit to the patient. Fluid balance was assessed by intake and output charts and daily weight recordings. She was confined to bed and on a standard ward diet so that other factors which might influence these observations were reasonably static.

A patient with hypertensive congestive cardiac failure and increased venous pressure might be assumed to have a low cardiac output, and be expected to respond to lowering of this pressure by increased cardiac output. This might be followed by beneficial diuresis. However, in this instance other factors are clearly not necessarily equal, because, apart from simultaneous lowering of the arterial B.P., the effect of methonium compounds on the rest of the autonomic nervous system can hardly be assessed clinically and may well be varied and profound. It is quite possible, indeed, that renal blood flow and glomerular filtration will be reduced, because this has been shown to occur with T.E.A.B. which also paralyses autonomic ganglia. This aspect of the problem is being investigated and will be referred to below.

In fact the administration of P.M.B. by intramuscular injection three times a day, to maintain a more or less continuous state of lowered blood pressure over a period of three days, had no effect whatsoever on the fluid output in this patient, nor was there any relief from her attacks of nocturnal dyspnoea. Nevertheless, as might be expected, an injection of a mercurial diuretic ("Neptal") resulted in a prompt and considerable diuresis, and dyspnoea was rapidly relieved. A subsequent course of injections steadily reduced the pulmonary congestion and peripheral oedema until water retention was abolished and the patient was able to resume her normal activities. Over a stone in weight was lost during the first four days.

A state of relative hypotension produced by penta methonium bromide was of no obvious value in the treatment of this patient. It had been explained to her that these observations were a preliminary to treatment and she was asked to comment on any sensations experienced. In fact there were none, and symptomatically she appeared unaffected.

DISCUSSION

It must now be considered whether it really is desirable to lower the blood pressure, at any rate by this means, in patients with established hypertension. Theoretically there are obvious advantages if symptoms related to the hypertension—e.g., headaches—can be relieved, left ventricular failure postponed, the chances of a stroke diminished, and renal function improved. It may be that the vicious circle of hypertension and vascular narrowing described by Wilson and Byrom (1939) could be broken. It is known that strain on the left ventricle may be relieved by sympathectomy, an enlarged heart may be reduced in size and abnormal E.C.G. changes reversed. On the other hand it may not be desirable to lower the blood pressure in hypertensive patients with cerebral symptoms of uncertain etiology. If there has been a cerebrovascular accident due to hæmorrhage, it would seem logical to lower the pressure to reduce the risk of a further episode, but if the trouble has been due to thrombosis the risk might well be increased by lowering the pressure. If the condition is due to vasospasm—a common supposition in cases of hypertensive encephalopathy—to lower the pressure would again seem desirable. But in particular cases

one often does not really know what the and there is no certain means of finding out

The Three Cases Reconsidered

In case 1 the patient died from pulmonary embolism during the second stage of his surgical sympathectomy, a most unusual happening. It had been thought that his breathlessness on exertion was somewhat out of proportion to the other evidence of hypertensive disease, but he had not had ischæmic pain, and cardiograms (including seven precordial leads) quite normal. Post mortem examination showed only thrombosis in the profunda femoris veins but very extensive coronary atheroma with much of the lumen. There were also several small myocardial infarcts apparently about ten days old. This must have been about the time of his first operation. He was up and about in the ward feeling extremely well from the third day, it seems probable that these small areas of infarction developed during the course of the first operation when for a time his blood pressure unduly low (as reported by the anaesthetist). It will be that the venous thrombosis in the leg, which not evident clinically, developed at the same time. If myocardial infarction can occur under such circumstances, it is at least conceivable that the same might have happened during a spell of undue hypotension induced by methonium compounds.

In case 2 the patient was a schoolmaster who had symptoms probably due to vasospasm, for which reduction of blood pressure would presumably be beneficial. As a matter of fact we do not yet know the effect on cerebral blood flow when widespread vasodilatation is produced by this group of drugs. It may well be that hypertensive attacks are sometimes based not on vasospasm but on small cerebrovascular accidents. Post mortem, multiple areas of cerebral softening are often seen and cannot be related to localised cerebral arterial occlusions. Such areas may well result from temporary slowing of cerebral blood flow with resultant irreparable damage to the delicate brain cells. Yet symptoms which can be related to these episodes are often short lived and clinical evidence of residual damage is slight or absent. On other occasions a patient who has had an apparent vasospastic attack subsequently succumbs to a manifest cerebral thrombosis. Clinically the exact pathological state cannot always be judged with accuracy, and errors in treatment are therefore possible. It is wise to attempt reduction of the blood pressure in patients such as this schoolmaster. During the day when he was maintained in a state of permanent lowered blood-pressure, he certainly felt less well. His body was presumably adapted to his hypertension, or possibly the hypertension had become a necessary accompaniment of his arteriosclerosis.

The third patient had had temporary loss of vision in the right eye, followed shortly afterwards by blindness in the left eye which proved to be permanent. She sought advice two years later because of what she considered to be premonitory symptoms in her good (right) eye. Her fears were natural enough. Optic atrophy in the left eye was evidently based on occlusion of the retinal artery, but whether this was really due to spasm or to thrombosis was merely guesswork. Dr G.I. Scott informed us that spasm for twenty minutes or so would probably be followed by permanent blindness. A drug capable of relieving such spasm, if easy to administer, would be valuable indeed. But if the catastrophe was really due to retinal artery thrombosis, lowering the blood pressure might be disastrous. Experiments with powerful drugs must not be lightly undertaken.

No New Era of Treatment

The cases discussed have been selected to illustrate as many facets of the problem as possible and no attempt

made to mask the difficulties. In fact, emphasis is placed on them deliberately lest it should be that a new era in treatment has come. There is so very many patients in whom symptoms of hypertension cannot be relieved by other means. Undoubtedly, however, there are some, these, especially when the hypertension is severe, symptoms disabling, methonium compounds are of trial. They usually relieve symptoms so far this relief is due to the drug and how far concomitant rest and relative freedom from domestic affairs is not always easy to determine. Perhaps in such cases it would be best to discard sphygmomanometer and try to find a dose of pentamethonium bromide which will relieve symptoms without unpleasant side-effects. Patient and practitioner then may be able to decide. In the long run, perhaps, the scientific approach is important.

Dynamics

essential hypertension, at least until advanced stages are reached, cardiac output is unaltered, and surgical sympathectomy there is no material change, whether or not the blood-pressure is lowered (Miles et al. 1941, Smith et al. 1946, Wilkins et al. 1949) must mean that the total peripheral blood flow is unchanged by operation and that any local change in flow must be compensated for elsewhere. In adjustments of flow throughout the body must be balanced.

In hypertensive patients, sympathectomy causes significant changes in blood flow through the kidney (Moran and Page 1941, Selzer and Friedman 1941, Miles et al. 1942, Foa et al. 1943, Talbot et al. 1943) when the arterial pressure has been lowered by operation. It is possible that renal flow may be maintained by local vascular adjustments in the kidney resulting in decreased resistance. Alternatively the fall of general arterial pressure might be due to such decreased resistance. These problems are not yet solved. It has been reported in Stockholm that glomerular filtration, renal blood flow, and the excretion of urine are reduced by an action of T.E.A.B. in normal persons (Aas and Blegen 1949). If this is true of patients with hypertension, methonium compounds may well have a similar reverse effect.

Cerebral blood-flow has been shown to be normal in complicated cases of hypertension (Kety and Schmidt 1948, Schenberg 1950). The relief of headaches by sympathectomy has been attributed to restriction of cerebral blood flow (Fishberg 1948). Certainly vasomotor constriction occurs in the upper limbs after this operation. Despite more than ten years' study, the hemodynamic effects of surgical sympathectomy are not yet thoroughly understood, nor are the reasons for success or failure known. When a fall of arterial pressure does occur, it is not even certain that this can be directly explained by dilatation of the splanchnic bed (Wilkins et al. 1949). In patients under treatment with methonium compounds, the blood-pressure falls considerably. Observations on cardiac output and blood-flow through various organs will therefore be of great interest. Such studies could certainly be made before there is any general tendency to treat patients with hypertension with these agents.

Actions and Side effects

With "medical sympathectomy" produced by the action of a drug which paralyzes the transmission of nerve impulses through sympathetic and parasympathetic ganglia the effects on the body may be widespread. Actually, with the doses employed to lower the blood pressure to a satisfactory level, there is usually little

obvious effect on other parts of the body such as the bladder or bowel. Some patients have gastro intestinal upsets in the form of constipation, looseness, or distension. Some complain of a vague feeling of general malaise, and others of dryness of the mouth and slight mistiness of vision.

Postural hypotension is the chief problem, and alarming collapse has been reported twice in patients under investigation elsewhere. Assessments should therefore always be made in an institution in the first place, so that over-reactors will be discovered. During this period adrenaline should always be at hand.

Effect of Posture

It must not be assumed that because with the patient recumbent an injection causes little apparent effect on the blood pressure the drug is not having any action.

Fig 7 shows the results of observations in one case. 50 mg P.M.B. was injected intravenously with the patient lying on her bed with no apparent effect. Accordingly a further 50 mg was given again with little effect. Slight fluctuations in the resting B.P. may be related to the natural reactions to repeated B.P. recordings and the manipulations needed for the injections together with the activities of an ophthalmologist who was endeavouring to study the effects on the retinal vessels. She

was then asked to sit up, whereupon the pressure fell promptly. On lying down again it gradually rose to the previous levels.

Another patient who was up and about was given a single dose of 5 g P.M.B. by mouth and the

Fig 8—Effect of posture eight hours after 5 g of pentamethonium bromide by mouth.

pressures were recorded at intervals throughout the day after lying down (fig 8). Twice during the evening the pressure was recorded before she lay down, and as can be seen from the figure considerable postural hypotension was still evident.

Tolerance and Intolerance

It is difficult to be sure about the development of increased tolerance to the drugs, but the evidence suggests that it may occur in some degree. No instance of idiosyncrasy has been observed.

Choice of Preparation

As regards investigation and treatment, we have found little difference between the four preparations used—the iodides and bromides of pentamethonium and hexamethonium. Pentamethonium bromide, which

we have chiefly used, and which is probably the most suitable preparation at present available, is unfortunately hygroscopic and this precludes its manufacture in tablet form

Administration

For parenteral therapy, ampoules have been used, or else the powder dissolved in distilled water and sterilised by heat. Intramuscular injections are not painful. For oral therapy appropriate amounts of powder have been administered in a flavoured aqueous solution. This is not unpleasant to taste. Tablets or an elixir would be an obvious advantage and the latter is likely to be available shortly.

100 mg of r m b is a suitable intramuscular dose to give to an adult of average weight to see whether the hypertension is labile. If this is the case, the injection may be repeated two or three times during the day at appropriate intervals. 1 g of r m b is a suitable dose to give by mouth in the first place and if insufficient 2 g may be tried the next day. Thereafter 1, 1.5, or 2 g t.d.s. has been found the most generally useful régime.

CONCLUSIONS

The methonium drugs have as yet no place in the routine management of patients, though they may prove useful in the treatment of resistant symptoms related to hypertension. We need more information about their precise action, and for the present it will be most profitable to study, in detail, patients who might otherwise be treated by sympathectomy.

There is no evidence as yet that continuous reduction of blood pressure by drugs which paralyse the autonomic ganglia will prove beneficial in the long run to hypertensive patients, and it may well prove harmful to some of them. Even if desirable, it is not easy to achieve with the drugs investigated. On the other hand, there is no reason to doubt that other more efficacious and perhaps more selective preparations will be made, and possibly a study of the methonium compounds will throw light on the aetiology of essential hypertension.

Thanks are due to Messrs May & Baker for generous supplies of these preparations, and to Dr W. R. Thrower, their consulting physician, for his constant interest and advice.

PENTAMETHONIUM IN HYPE

STEPHANIE SAVILLE

M.B. Dublin

HOUSE PHYSICIAN, ST MARTIN'S HOSPITAL, DUBLIN

For many years a clinic for hypertension has been held at St. Martin's Hospital, and some of the cases have now been observed for a long period. Some needed treatment, others none. Many with "benign" hypertension of varying degree have had headaches, giddiness, failing vision, breathlessness, and other symptoms, and examination has revealed arterial degeneration, retinal changes, and in some cases renal failure. The customary treatment has been in bed, sedation, and regular venesection, but patients have failed to respond significantly and to maintain initial improvement. Recently some with serious symptoms, who were not responsive to these measures, have been treated with pentamethylene bistrimethyl ammonium, called pentamethonium, in the form of its bromide salts. None were cases of "benign" hypertension.

At first the patients were admitted to hospital, already inpatients, to permit accurate recording of progress. Later, however, some were successfully treated as outpatients or were able to continue treatment at home. The aim throughout has been to lower blood pressure enough to relieve symptoms but not enough to provoke others due to hypotension. At present there seems to be no way of foretelling response, and treatment has to be arranged individually. In actual fact, however, none of the five cases treated to date has failed to obtain relief from symptoms. As might be expected, subjects with inelastic vessels do not show, and do not require, the striking fall in blood pressure seen in the more labile type of patient after the use of the new drug. Throughout the investigation blood pressure records—whether hourly, daily, or weekly—have been taken as nearly as possible under standard conditions. Except in special circumstances no dietetic restrictions have been imposed.

ADMINISTRATION

At first we injected the pentamethonium salts (as the bromide) intravenously, in doses of 10 mg dissolved in distilled water, but the effect was too sudden and too short. We therefore gave the drug by intramuscular injection, and subsequently by mouth.

Our present practice is to test the initial response by giving one or two doses of 50 mg intramuscularly, then to start daily treatment by mouth. The dosage varies, but is usually 0.5–1.0 g every four, six, or eight hours. The first dose should be taken as early as possible in the day. We have found no significant therapeutic difference between the bromide and iodide salts.

By mouth the drug is most conveniently taken in the form of a flavoured aqueous solution. As pentamethonium bromide is deliquescent, no wholly satisfactory tablets have yet been made.

CLINICAL RESULTS

The following notes show how the five patients responded.

Case 1.—Mr A. aged 63, had been attending for 10 years with headaches, giddiness, insomnia, and depression. He had moderate arteriosclerosis with retinal changes, his resting blood pressures averaged 200/130 mm Hg.

Treatment with pentamethonium bromide was started Dec. 8 1949. He was given 10 mg intravenously and three minutes later it had risen to 220/140 to 205/110. Ten minutes later it had risen to 220/130. A further dose of 10 mg intravenously produced readings of 195/130 at the end of January, when enough pentamethonium was available to permit uninterrupted treatment, 400 mg was given

three times a day, and during the whole of February remained about 235/125. His symptoms began to abate and he was soon able to sleep without barbiturates. In March an attempt was made to produce a more accurate curve by giving 300 mg orally four times a day. This produced a B.P. of 215/100 one week later, and after further treatment an average B.P. of 210/100 over a month.

At this juncture, for a short time he was unaided without treatment, but though his B.P. was once again his symptoms did not return apart from occasional headaches.

Throughout April, May and June treatment was continued with 300 mg four times a day. His resting systolic B.P. lay between 220 and 240 but his diastolic pressure remained remarkably constant at about 110 compared with an average of 130 before treatment. His headaches and other symptoms have disappeared and now he feels and certainly appears a different man. His discs still show the characteristic changes of senile hypertension but his vision has improved.

Case 2—Mrs B, aged 42, had been treated since 1945 for hypertension of a malignant type with symptoms progressively worsening until January, 1949 when she became bedridden. After lying in bed for five months, with severe headaches she began to have encephalopathic attacks and was admitted to hospital on Oct. 1, on which day she had fits.

On admission she was conscious but depressed and inoperative. Her blood pressure was 240/140 she had marked changes with papilloedema and deteriorating vision. tendon reflexes were exaggerated and the plantar response extensor on both sides. After venesection her condition improved, though her right arm was still weak and the right ankle reflex positive. Power in her right upper limb had returned by Oct. 11 but she still had a right foot-drop and exaggerated reflexes on the affected side. Her B.P. was sometimes as low as 170–190/100–110 but generally varied between 210/110 and 240/140 and on one occasion reached 300/160. In November she was having encephalopathic attacks almost daily, each lasting about fifteen minutes during which time her limbs twitched and she was noisy. Pentamethonium was considered but she refused operation and left hospital on Dec. 7. On Dec. 24, 1949, she had such severe fits at home that she was readmitted to hospital, and after a few days palliative treatment she was discharged. On Jan. 5, 1950 she was readmitted for treatment with pentamethonium. Her average blood pressures were then 290/140 and they stabilised at about 180/120 on regular intramuscular injections of 30 mg every six hours.

During February she was given 300 mg of pentamethonium bromide by mouth every eight hours and her B.P. averaged 90/110. She said she felt infinitely better, and she became well enough to be treated as an outpatient, having had no further cerebral attacks. In early March, while still very well, with her B.P. remaining at about 180/120 she was unable to obtain the drug for five days and had to be readmitted with a severe encephalopathic fit the only one since treatment started. Her B.P. had risen to 230/170. On her recovery treatment with pentamethonium bromide was recommenced 10 g being given by mouth four times a day. She improved enough to return home by the end of April. She was free from headaches and sleeping normally, having an average B.P. of 190/115.

Shortly afterwards she had a 'swimming' sensation on waking in the morning—presumably due to postural hypotension—and some difficulty in reading due to the mydriatic effect of pentamethonium. By May however, the side-effects of treatment had disappeared and her B.P. was 180/125 at rest. The daily dose of 10 g four times a day was continued. Early in June (B.P. 210/130) she developed what appeared to be a bromide rash on the posterior surface of her legs so 5 minims liq. arsenicalis was added to each dose of her mixture with good effect. She remained free from ocular symptoms but ophthalmoscopic examination revealed the characteristic features of malignant hypertension. She remains generally symptom free and is able to move around the house in a restricted manner.

Case 3—Mrs C, aged 57, had been under observation for ten years with essential hypertension for which she had been taking increasing amounts of barbiturates—sufficient to make her permanently drowsy. She was a donor for the blood bank and was bled regularly.

During 1949 her general condition deteriorated and she developed gross retinal changes being unable to read headlines

after June. In October she was admitted with congestive heart-failure, her average B.P. being 220/150. Despite treatment her oedema persisted and her B.P. in December was 230/145. Intramuscular injections of pentamethonium bromide 50 mg at first produced excellent results her B.P. falling from 240/140 to 150/80 in one hour. Taken at subsequent hourly intervals the readings were 160/70, 160/90, 200/100, 190/100 and 160/100 four hours later they had risen to 240/120.

After a period of intramuscular treatment with good effect 0.5 g was given orally three times a day. Her headaches disappeared her oedema resolved, and at the end of February she was fit to get up and later go home with her B.P. stabilised at about 200/110. She could now read a letter. She was able to lead a restricted life at home but did not take her pentamethonium bromide regularly and was not seen until March 30. Her B.P. was then 200/130 her heart was still enlarged, and there was slight oedema in the legs. The improvement in her vision had not been maintained and there was a new patch of exudate in her right eye. She was encouraged to continue treatment with pentamethonium, but owing to distance she has not attended for examination.

Case 4—Mrs D, aged 41, had long been under observation with a slowly progressive hypertension, which had made her an invalid for the past eight years. She had been bedridden since 1945 but was admitted to hospital from time to time for a check up and possible treatment. In recent times her principal complaints had been giddiness, headaches and swelling of the legs.

In December, 1949, she was admitted with signs of hypertension and congestive heart failure her B.P. being 240/120. Treatment with pentamethonium bromide was begun and after some experimental doses 0.5 g by mouth four times a day was found most suitable. The effect was to stabilise her B.P. at about 180/100 the signs of congestive failure disappeared and she was discharged from hospital in March. She is now up and about at home.

Case 5—Mrs E, aged 60, came under observation early last May, with two months' history of severe headaches, insomnia and breathlessness on stairs. She had continued normal activity until one morning she collapsed in chapel, and ten days later she had become unconscious while shopping. She was found to have palpable radial arteries, early changes in the retinal vessels and a B.P. of 220/140, radiography showed cardiac enlargement with dilatation of the aorta.

Receiving oral therapy from the beginning, she was put on 0.5 g pentamethonium bromide every six hours as an outpatient. The systolic pressure fell to an average of 190 and the diastolic pressure to about 120 at which levels they remain. Her general condition has strikingly improved, she is now free from giddiness and is sleeping well, and her breathlessness has ceased. She has resumed work, continuing to take 0.5 g of the drug every six hours.

The principal side-effect to be watched for is postural hypotension. With experience in adjusting the amount and time of dosage little trouble has been encountered, but all patients are instructed to assume the erect position by easy stages and to sit down if they have any prodromal symptoms. In two patients pentamethonium has caused a transient interference with visual accommodation and in another some conjunctival congestion. One patient developed a bromide rash. No evidence of impaired renal function attributable to the drug has been observed.

DISCUSSION

Though no case of malignant hypertension in a young person has come under observation, the cases cited are representative of the common types of hypertension requiring treatment. It will be noted that the initial improvement obtained with pentamethonium was maintained in all but one (case 3). The original state of this patient was so grave that symptomatic relief was the most that could be expected. Whether in fact pentamethonium can reverse a steadily progressive condition time alone will show but it is conceivable that early and assiduous treatment will improve the prognosis. In the other patients described severe symptoms have been relieved

for as long as six months, and there is no sign that the drug is losing its effect

In the early stages of this investigation close attention was naturally paid to blood pressure records. There is no doubt that blood pressure levels can be influenced almost at will by means of the drug, and its effect on the diastolic pressures is highly important. But it became evident that its real value lies in its ability to relieve, at least temporarily, symptoms which are not only distressing to the patient but are of grave medical significance. Systolic pressures may at times be not appreciably below pre-treatment levels, but this does not seem to affect the symptomatic relief. In case 1 the systolic readings after six months are little short of the

average before treatment started, but the pressure remains lower, and the sustained " in general condition is striking

CONCLUSION

The results in 5 patients suggest that pentamethylenetetrazol bromide may be useful in the treatment of at least some forms of hypertension. In all these cases it has relieved troublesome symptoms and has apparently arrested the progress of the disorder.

This investigation has been made possible by the co-operation of Dr C D Cross and other members of the staff of St Martin's Hospital, and thanks are due to Messrs May & Baker Ltd. for supplies of the compounds used.

Reviews of Books

Major Symptoms in Clinical Medicine

JOHN ALMEYDA, M R C P, senior registrar, Royal Chest Hospital, London. London: Henry Kimpton 1950. Vol 1. Pp 378. 25s.

THIS is the first of two volumes designed to combine, for the assistance of examination candidates and busy practitioners, the anatomical and physiological explanations of symptoms, together with their significance and the mode of their investigation. Dr Almeyda has endeavoured to separate objective from subjective symptoms, prefacing each section in the book with a short description of their anatomical and physiological background, their mechanism, and their classification. The inclusion of separate chapters on lassitude and nervousness and on hiccup will be welcomed by most readers. Many of the illustrations are case-photographs borrowed from other works. These are supplemented (not always happily) with some of the author's own cases, with an ambitious collection of heavily overdrawn sketches to emphasise characteristic faces, and with numerous poor quality diagrams and line drawings. It is a pity that the standard of illustration falls so far below that of the general production.

Fundamentals of Psychoanalysis

FRANZ ALEXANDER, M D, director, Chicago Institute for Psychoanalysis, clinical professor of psychiatry, University of Illinois. London: Allen & Unwin 1949. Pp 312. 16s.

Professor Alexander's book on *The Medical Value of Psychoanalysis* was due for revision; he decided to write a new book instead, of which this is the first part, the second part will deal with the psychosomatic approach to medicine. He no longer thinks it necessary to trace the historical evolution of Freudian theory; he abstains from reproducing elaborate case histories, and he devotes his efforts mainly to the presentation of fundamental theory and its application to treatment. In respect of instincts or drives, however, he avoids theoretical discussion about the ultimate nature of these forces. The book is an admirable account of psycho-analysis as taught in the Chicago school: the language is clear, terms are used with as much precision as the subject matter allows, and there are only occasional lapses into the weakness of claiming too much. After introductory chapters on the position of psycho-analysis in medicine and the nature of psychological understanding, Dr Alexander sets out a somewhat original view of the basic principles of psychodynamics—the principle of stability (the psychological equivalent of homeostasis), the principle of economy or inertia (corresponding in large measure to Freud's "repetition compulsion"), which permits energy to be conserved, and the principle of surplus energy, which is a source of sexual activity and therefore of reproduction. Expositions of sexuality and the functions of the ego are followed by a consideration of the sociological factors which influence personality development. Chapters on the psychology of dreams, wit and aesthetics, psychopathology (as studied in the phenomena of mental illness), and the principles of psychoanalytic therapy conclude the book. The chapter on therapy reflects the modifications of standard Freudian

procedure which the Chicago analysts have developed within the last few years, especially their insistence that emotional experiences outside as well as within the therapeutic situation are the main therapeutic factor. A well-selected bibliography, not restricted to psychoanalytical writings, appears at the end of each chapter.

Atlas of Drawings for Chordate Anatomy

SAMUEL EDDY, professor of zoology, University of Minnesota. London: Chapman & Hall 1949. Pp 184. 28s.

THIS atlas, elementary in scope, consists of semi-diagrammatic unlabelled drawings of dissections of representative chordates, most of which are obtainable in this country. Illustrations are included of the nervous, vascular, reproductive, digestive, and muscular systems. Their object is to assist the dissector, and to save the time he usually spends in making his own drawings. However, Professor Eddy's belief that the labelling of supplied drawings will impress the dissected structure on the student's memory and stimulate his understanding of it will probably not be shared by all teachers. Most of the drawings are accurate and fairly clear, but they will certainly need to be supplemented. For example, there are diagrams of the brain and the brachial plexus, but no indication of the destination of the nerves arising from them. In spite of such deficiencies, the book will have its value in supplying a class with diagrams not readily procurable elsewhere.

Clinical Chemistry (4th ed. Philadelphia and London: W B Saunders 1949. Pp 642. 40s.)—This well known textbook by Prof Abraham Cantarow and Mr Max Trumper, M D, shows evidence of revision in the chapters dealing with carbohydrate and protein metabolism, renal physiology, and endocrine glands. New material has been added on liver function tests, renal injury in the crush syndrome, potassium therapy, methods of investigating adrenocortical function, and the like, most of which are not recent observations. The last cover page appropriately tabulates the normal chemical standards (incidentally, the standard urea clearance should be 54 instead of 74 c cm). The field of clinical biochemistry is covered well; the book is easily read, and there is a good index.

A Short Textbook of Surgery (5th ed. London: J & A Churchill 1950. Pp 676. 30s.)—The new edition of Prof C F W Illingworth's well known textbook includes recent advances in the surgery of the blood vessels, and new sections on pulmonary stenosis and portal hypertension. The section on treatment of infections of the fingers and hand—a subject constantly evolving—has been altered considerably to chime with modern views, and there are many minor amendments. One new plate and several new figures have been added, but one or two of the old ones still need revision. Like many another British author, Professor Illingworth has striven successfully to keep the size of his book in bounds; indeed, he has pruned so ruthlessly, he tells us in his preface, that he has even saved a few pages—four to be exact.

ELSEVIER'S ENCYCLOPEDIA—Owing to devaluation the price of this work to subscribers (see *Lancet*, July 8, 1950, p 58) has had to be increased to £9.

QUINIDINE IN DISORDERS OF THE HEART—The English publishers of this book which was reviewed in our issue of Aug 5 (p 214), are Cassell & Co. and the price is 10s.

Back to the Land

In agriculture the replacement of the horse by the tractor and the use of power on the farm have given a new impetus to development. In England and Wales the total farm supplies of power (excluding transport) rose in just over one million horse power in 1908 to two million in 1939 and five and a half million in 1948. Of this power provided 87% in 1908, 25% in 1939 and only 7% in 1948. Sir HAROLD HARTLEY, F.R.S. in his presidential address to the British Association in Birmingham

the British people tend to cherish their farmers—their soldiers—only in times of war. During peaceful intervals agriculture seems to many townspeople a backward industry kept alive only by statutory subsidies. A very different idea is conveyed by EASTERBROOK'S review,¹ which he has done with the help of the economic information unit of the Treasury and of other Government Departments.

In the first half of the nineteenth century the world master of British farming was undisputed, but hard times followed. "With a flexibility which probably other great industry could claim, British agriculture has achieved a series of fundamental changes to meet variations in which the dice always seemed loaded against the home farmer," says EASTERBROOK. "First of all, then grain and later meat came rolling into the ports, all produced at small expense from the vast estates of virgin land which our capital, our railways, and our steamships were opening up overseas. In France and Germany, in fact in most of Europe, governments protected their farmers against such competition. The virgin territories of the New World were exploited without thought for the future. After a few years the soil was made to yield its riches, and nothing was put back into it." Yet even in the last half of our beef and half our mutton came from our own soil, together with almost all our potatoes, half a quarter of our cheese, and a third of our meat. By now, however, farmers had "settled in into that attitude of inferiority which seems the inevitable lot of the poor relation." Yet they still believed that one day the country would need them again. And so it did. Between 1939 and 1943 wheat production in the United Kingdom rose from 1½ million tons to 3½ million tons. The harvest of barley, oats, and other grains rose from 4 million to 5½ million tons, potato production was doubled, and the milk-supply was kept up despite the loss of 1 million acres of grazing and almost all the imported cake. Since then some of the enthusiasm which delayed this feat has inevitably been dispelled, but output per man is by far the highest in Europe,

and no other country has such a concentration of tractor power.

Today there is good reason—apart from special war-time risks—for the nation to foster its agriculture as never before. Until the late war began, food was bought cheaply in the world market in exchange for British manufactures, but the cost of imported food has risen because of the relative devaluation of our manufactured goods, due to world industrial production rising much more sharply than food production. Thus we now depend on the skill of our farmers no less than on that of our manufacturers, the export drive is more publicised than the effort to produce more food, but the O.E.E.C. concluded that the most promising way of saving dollars was by agricultural expansion.² Such expansion will require stern effort. This week Prof H. D. KAY, F.R.S., who is president of the section of agriculture of the British Association, said: "Were every pole of deserted land brought back into cultivation and the utmost—consistent with economic sanity—done with other marginal land, we could not raise production at home from its war-time peak of some 40–42% of our food requirements to the 50%, or even more that is our first objective, without growing at least 20% more food per acre on a very substantial proportion of our present cultivated area." As a dairy farmer, THOMPSON³ has named these as the most important factors contributing to better farming: disease control, controlled marketing and the distribution of knowledge through the agricultural press and the National Advisory Service. Efficient costing he also rates highly. Modern farming thus calls for varied knowledge and a receptive mind and Professor KAY suggests that one way to promote further expansion would be to help scientifically trained and practically minded young men who lack capital to start farming on their own. He believes that the best hope of greater production is by full application of scientific and engineering knowledge and of modern methods of management. Evidently, though our fields have already yielded more than some would have believed possible a decade ago, the limit has still to be reached.

Aortic Embolectomy

SADDLE embolus of the aortic bifurcation is a comparatively rare but highly fatal condition. About 200 cases have been published, and, since most of them were associated with serious heart-disease, it is not surprising that three-quarters of the patients died immediately. There must be many more unrecorded cases, and the immediate mortality-rate is probably even higher than this. A typical case is easily recognised: the patient with auricular fibrillation or recent myocardial infarction suddenly collapses, and there is pain, pallor, paralysis, pulselessness, and paraesthesia in both legs. EWING,⁴ however, emphasises the difficulty of diagnosing cases with an insidious onset and the importance of observing carefully the physical signs of arterial insufficiency. Even if the patient survives the initial catastrophe he is likely to die from shock, cardiac failure, or further embolism, and treatment is usually unavailing. Nevertheless, 26 "cures" have been reported after embolectomy,⁵ and

¹ See *Times* Dec. 1 1949.

² Thompson J. H. *Farmers Weekly*, July 25 1950 p. 53.

³ Fwing M. R. *Brit J Surg* 1950 38 44.

⁵ Albright H. L. Leonard F. C. *New Engl J Med* 1950 242 271.

13 further patients, including EWING's 2, have survived the operation. There have been 8 more "cures" by conservative treatment (including sympathectomy) alone and 4 spontaneous recoveries.

How, then, should a particular case be treated? The initial shock should be treated with morphine alone, for patients with serious heart-disease do not tolerate rapid transfusion. If the response to morphine is good, the decision must be taken whether or not to operate, and both EWING in London and ALBRIGHT and LEONARD in the U.S.A. advocate embolectomy if the patient seems fit to stand the operation. It should be remembered, however, that there have probably been several unsuccessful attempts at embolectomy which have not been reported. Moreover, there is a growing tendency⁶ to treat emboli in general conservatively, on the grounds that they are often multiple and the patients do not survive for long, that thrombosis often occurs at the site of the embolectomy, and that modern conservative measures, if properly applied, give as good results as surgery. If embolectomy is decided on it should be done as soon as possible, preferably within six hours. Either general or spinal anaesthesia may be used, and both have the advantage of opening up collateral vessels by causing peripheral vasodilatation. The aorta and common iliac vessels are best approached through the abdomen, with the patient in the Trendelenburg position. If the embolus cannot be felt, the lower limit of aortic pulsation will indicate its position. The posterior peritoneum is incised and rubber tubes are passed round the aorta and common iliac vessels to control bleeding. Those round the iliac vessels should only be tightened if this is necessary, because one cannot be certain of the lower limits of the embolus and there is danger of breaking it up. It has been usual to incise one iliac vessel and extract the embolus in one piece, if possible, or piecemeal by "milking" it round from the other vessel. But this procedure, as in EWING's cases, often produces serious narrowing of the vessel when the incision is sutured, and it seems better to make the incision directly into the aorta immediately above the bifurcation. When the embolus has been extracted, the incision is sutured with an arterial ligature, taking care not to penetrate the intimal coat. Local haemostatics are applied if needed.

Various other measures may be useful either instead of or in addition to embolectomy. The heart must be controlled with digitalis, &c., and oxygen may be needed. Heating and elevation of the legs must be avoided. Most people advocate heparin and dicoumarol or heparin alone, with proper laboratory control, to prevent thrombosis spreading from the site of the embolus. Papaverine has been used extensively as an antispasmodic, but the penta and hexa methonium compounds which can be given by mouth, may largely replace it. Paravertebral procaine block of the lumbar sympathetic chains and spinal anaesthesia involve a risk of serious bleeding if anti-coagulants are used at the same time, the methonium compounds may make these measures unnecessary. After the acute phase has passed, and if the cardiac condition is good, bilateral lumbar sympathectomy may be considered. ALBRIGHT and LEONARD suggest that this may be performed at the same time as embolectomy. However, it is important to remove

the first lumbar ganglia, so as to produce a division in the collateral vessels at the region of the aorta, and these cannot be reached through a small incision. Division of the lumbar chain lower down aggravate the condition of the legs by vasodilatation below the level of the block. Amputation will, of course, be necessary if becomes gangrenous.

Agreement will not be reached on the best of treating this uncommon condition unless who encounters an example records his. It is especially important that the failures and the successes should be widely published.

TRENDS IN GENERAL PRACTICE

In England and Wales general practitioners are becoming more evenly distributed. In the report to the Minister of Health on its second year's work, the Practices Committee prophesies that this trend continue "until a state of equilibrium is more reached." A simple formula is required, to focus attention on areas which need extra doctors more urgently. The number of patients per doctor suggests "in the areas," the report says, "doctors have lists well the average together with large mileage and are often obliged to dispense medicines for patients. In addition some of the doctors are in contact with the Regional Hospital Board or a Hospital Management Committee for a varying number of weekly sessions. The overall work of these practitioners may exceed that of many doctors with full lists in urban areas." It is also the factor of the varying level of demand for medical care in different areas.

During this second year of the service 1242 were admitted to medical lists, and 912 were replaced. The number of doctors newly entering into partnership with established practitioners was 374. Replacement vacancies totalled 690, and 178 assistants succeeded in becoming partners of, their former principals (this figure does not include assistants appointed as replacements to other vacancies). Of 266 applications to start new practices, all but 6 were granted. On Jan. 1, 1950, the number of assistants was about 1700. Some who started practice in the more popular districts "to have little prospect of ever achieving a position in their present location." London seems to be particularly difficult area, and the committee suggests that parts of it should be "closed" to entrants. The report notes regretfully that wishing to start new practices are often balked by difficulty of obtaining suitable premises. Though local authorities are coöperative, this applies as to the new development as to the built up area. General practitioner services should, says the committee, be expanded as the new population movement is not be provided as an afterthought. As to practices, the outgoing doctor's premises have been obtained by a doctor other than the successful applicant for the vacancy—a procedure "calculated to naught the machinery of appointment to practice under the Acts and Regulations." However, a satisfactory solution is expected soon. The machinery for appointment to advertised vacancies has been criticised as cumbersome, but lately successors have been found over before the retiring doctor has withdrawn with death vacancies and withdrawals at short notice. "The vacancies are usually filled without a long delay and it has been possible to provide satisfactory interim arrangements for the care of the patients." Furthermore, the time taken by the Ministry to con-

le appeals has been greatly reduced. Under the onal Health Insurance scheme, a partnership t be recognised as such by an Insurance Com one partner's share was less than a third of e of any other partner. No similar regulation made under the National Health Service, and all but material percentage" of partnerships all outside this definition "may well prejudice ate of the true medical manpower in an area lermine the proper working of the allocation.

In other obvious respects such arrangements undesirable." It has been proposed that where enon is not satisfied the doctor should be treated, purpose of number of patients, as an assistant ig the year an experimental plan has been worked applying some of the money in the Special ment Fund to drawing doctors to the less attractive re heavily populated parts of a county area, and if ume is successful it may be repeated elsewhere.

EST NEWS OF THE PARTICLES IN MOUSE TUMOURS

essor Passey and his colleagues in Leeds are still ig the minute spherical bodies which they demon- three years ago¹ in extracts of tumours, normal, and milk from strains of mice which are parti- hable to cancer. Two years ago² they obtained ut photographs of these particles by electron copy and showed that their diameters ranged from 1200Å, with most of them about 300Å. These s have since been fully recorded and extended³ late sedimentation of particles in 2 hours is attained a ultracentrifuge at a speed equivalent to 120,000 gravity. The larger particles sedimented from ble chicken tumours and from some mammalian urs have been compared with those found in high r-strain mouse tumours and there is little similarity er behaviour.

re of the biological tests, which are being performed orrelate particle content with tumour-inducing ity have matured, but they are a terribly long job. idea of the patience required in biological testing be gathered from the fact that in one experiment ol mice have been kept alive up to 19 months e controls, which so delay the completion of the ments, are essential in establishing the infectivity herwise of the particles as a whole and in determining her any precise size range is associated with infec- y. Up to now the tests have shown a good correlation een the presence of particles and the induction of marv tumours and thus also indicates a correlation the presence of Bittner's agent. The particles were at or rare in mammary tumours induced with ivi cholanthrene in female mice, or with this carcino and oestrone in males, belonging to low-cancer, t-free strains.⁴ Extracts of these particle free urs produced a very few tumours in hybrid mice possible, however, that Bittner's agent was being ed by some of the hybrid mice used in the tests ulds⁵ and others previously⁶ noted. Both electron icroscopy and biological tests showed that the milk the stomach of suckling mice of a high-cancer n was a good source of both particles⁷ and agent⁸ y of these studies are preparing the ground for ar physical examinations of human milk. Unfor- tely, owing to the species exclusiveness of most ur viruses biological tests on mice will probabl- be of any value in determining the presence or ice of these agents in human milk.

DEAFNESS IN CHILDREN

THE parents of a deaf child are often bewildered and kept at strain because their doctor will not tell them point blank the unfavourable factors in the prognosis. He may not make it clear, for instance, that congenital deafness, being associated with maldevelopment of some part of the auditory apparatus, is incurable. Nor does he always reveal the hopeful factors in the case. He may even omit to allay at the outset the common fear that the child will be permanently dumb, or to explain that deafness is rarely complete, and that even the grossly deaf child will learn to talk under the guidance of trained teachers. And, having admitted that some types of congenital deafness are also hereditary, he may shirk direct questions about marriage and parenthood by mumbling that he really can't say.

But the worst fear often troubling parents is that their child is mentally defective as well as deaf, and here again the doctor may be far from reassuring. Indeed if he is not familiar with the progress to be expected of a congenitally deaf child the doctor himself may be deceived. It is of great importance to the child that his intelligence—which, like that of other children, may be high or low but is usually average—should be assessed early, and that he should be treated according to his ability from the start, at any rate by all who know him. In the course of his life he will again and again encounter those who fancy that because his speech is unusual his mental powers must be weak, but he will bear this embittering experience with equanimity if he has always lived among people who respect his intelligence.

The Deaf Children's Society have lately published a pamphlet,¹ written for educated parents by a consultant otologist, which brings out these points very well. The author sets out the causes of deafness, mentioning biological failure in development, virus and syphilitic infection of the mother during pregnancy, middle and inner ear infections in the child, meningitis and the exanthemata, adenoids, sinusitis, and otosclerosis which is occasionally seen in childhood. He distinguishes briefly the types and degrees of deafness, gives some useful pointers towards diagnosis, and explains modern methods of testing. The fact that deaf people are not dumb is printed in capitals. Among preventive measures, he urges the expectant mother to avoid, as far as possible, contact with german measles and influenza, and parents to report their children's ear troubles early to the doctor, and to see that they don't go swimming when they have a cold. On the question whether deaf people should marry and have children he says:

'If the parents suffer from congenital deafness, there is certainly a risk of a deaf child, if the parents are otosclerotics there is a chance of deafness being propagated to future generations, with other forms of deafness no risk is involved. We have no proof that marriage of healthy relatives (consanguinity) produces deafness in their children.'

After making it clear that many forms of deafness are incurable he mentions the value of treatment in otitis media and chronic tonsillitis, the enormous value of hearing aids and the good effects of early education and training.

The little booklet contains much that parents of deaf children are hungry to learn. It could have been simpler (terms like "Mendelian recessive character," and "abnormality of the genes" crop up without warning or explanation) but it is singularly informative, and shows a thorough understanding of the parent's unspoken fears. It might well be followed by a sequel telling something of modern methods of educating the deaf.

Dr. FRANK HOTTIS has been elected master of the Society of Apothecaries.

In England Now

A Running Commentary by Peripatetic Correspondents

YESTERDAY I came across a Registrar, curled up into a small ball in a corner of our hospital. He was sniffing and chewing the frayed ends of his shirt cuffs. His future, and the future of Registrars as a group, remains grim and uncertain, and I suggest that the following measures be applied immediately to lighten their gloom.

First, let the term Registrar be dropped from medical usage, the more suitable title of Consultoid will better support the tottering group. In the struggle of the years ahead the grading of a Consultoid should present no difficulty—starting as a Weenr one, he will be promoted through the ranks of Slight, Small, and Big, becoming finally an Eversobig Consultoid in the phase preceding his full maturity.

Secondly, commensurate with this promotion, let there be rules of dress which must be followed, to give him yet further support and uplift. The weenier Consultoid the more immaculate should be his costume, so he will start in a black coat and spongebag trousers, with a white paper collar—but by the time he reaches seniority he will be wearing an off-royal blue suit, brown shoes, and a sacking shirt with soft collar (undone) attached.

For something must be done to prevent Registrars from curling up in corners. It looks so untidy.

For once a congress really has opened in a blaze of glory. A few hours before the opening reception the Church of Our Saviour in Copenhagen, one of that charming city's most charming landmarks, caught fire. Tragedy was averted only because two energetic physiologists from North Britain, one an eminent professor, were climbing the tower soon after the fire began. They came on it in an upper room of the tower. Without a thought for personal danger one rushed for the fire brigade. The other, more practically minded, put the fire out with a supply of water he carries round with him for such emergencies. And fortunately, being interested in gastric function, he had spent his lunch-time investigating the properties of the products of the Carlsberg Foundation.

They are now national heroes. And England's prestige has received a boost which has almost counterbalanced the somewhat gloomy view taken by the Danes, as salesmen, of the visit of our Food Minister.

* * *

Human occupations may be divided broadly into two groups—first, small and select, the Those-you-send-for's, which include plumbers, doctors, vets, and on rare occasions parsons and undertakers; secondly, the Those you go to's, comprising shopkeepers, lawyers, civil servants, the teaching profession, editors, actuaries, bankers, farmers, and a hundred others. The question arises whether it is better to belong to the former obviously more socially important group or whether one pays too high a price for this enhanced prestige. I must have a word about it with the plumber.

* * *

The new admission turned out to be an elderly paranoid troubled with electricity which comes down from the sky like two sparks and gives her the cramp. The interview included the usual simple questions to test her school and general knowledge and intelligence. Silence or "I don't know" was the monotonous response to the school questions, in arithmetic and history we drew complete blanks. Then we got to geography—naming of capitals of countries. This was dull, too, till we got near home. "Capital of England? America, of course! That's the trouble, isn't it?"—School and general knowledge defective, but intelligence? I wonder.

Not good,
And untrue
That's why Conservatives make me see red
Socialists make me feel blue

Letters to the Editor

ACCURACY IN RED-CELL COUNTS

SIR—Your leading article of July 15 and 16, 1934, from Dr Jennings in your issue of Aug. 5, makes it clear that a rational approach to blood counting will be possible, but there are many points on which pathologists will disagree.

First, the use of the colour index. This is a measure of the average mass of haemoglobin in a cell, but since it is based on assumed average values which vary between the sexes, with age, and geographical location, it should be replaced by mean corpuscular haemoglobin (MCH), which is independent of sex and location. Even the two independent variables—cell volume and the globin concentration within the cell. For these two independent variables must be estimated. The second of these is easily and precisely estimated from haemoglobin and haematocrit determinations. Measurements of cell volume are much less accurate. Although in the diagnosis of pernicious anaemia measurement of cell diameter is useful, it is by no means absolutely reliable, for I have seen several other cases of anaemia which show very similar patterns. I can be no doubt that the only reliable procedure for diagnosis is to estimate cell volume and haemoglobin concentration as accurately as possible, and then to examine the stained film with the greatest care. A stained film, though usually reliable, can be misleading owing to alterations in the stain.

Second, the use of capillary blood. Petersen and Strangeways have shown that although the coefficient of variation of sampling from the finger is only occasional differences up to 10% occur, and I find differences of 5% between successive drops of blood common. For diagnosis, therefore, it is essential to obtain a sample of blood which can be well mixed. Sub-sampling, and this is best done by using a syringe, and this is best done by using a syringe. Blood according to the Wintrobe technique. Even diurnal variations of 7% in absolute levels may place, but these diurnal variations will not affect the size of cells or their haemoglobin content and will not interfere with diagnosis.

Despite Dr Campbell's example (July 20, 1934), the possible errors in counting are enormous. A British Standard Sytometer certified to comply with British Standard specification no. 748 has a tolerance of $\pm 5\%$, and a pipette $\pm 3\%$. The error of enumeration varies between 3% and 7% according to the density of cell suspension, and then the innumerable personal variations arise. The problem of random sampling have to be considered. During the last two years I and one assistant performed 317 counts on healthy men in such a way as to eliminate any bias, the haemoglobin estimation standard deviation less than 2% and applied to 500 cells were counted in each case. The colour index and MCH were as follows:

Colour-index	Frequency	MCH (M)
0.80-0.849	0	23.9-25.09
0.85-0.899	7	25.1-26.49
0.90-0.949	61	26.7-28.09
0.95-0.999	57	28.1-29.59
1.00-1.049	78	29.6-31.09
1.05-1.099	68	31.1-32.49
1.10-1.149	28	32.5-34.09
1.15-1.199	12	34.1-35.79
1.20-1.249	4	35.8-37.49
1.25-1.299	2	37.5-39.09

317

Analysis shows that the distribution departs from normality, while nearly a quarter of the counts

sults greater or less than the generally accepted 'normal' mean. It is obvious that some considerable change in the number of calibrations is necessary. If the number of calibrations is reduced and the measurements either simplified or fewer, then accuracy should improve and with a balance which may be placed on the count. Both the Ford instrument and that made by Metropolitan satisfy these needs. In the former the chamber led and the critical calibrations are cell depth and 10 of two apertures in the eyepiece, in the latter a calibrated apparatus is needed. It seems that either case Bürker's technique should be used—that oil should be measured in a capillary pipette, added into a volume of fluid measured by an automatic pipette, and a drop transferred into the chamber of the Ford apparatus or an aliquot measured into the Metropolitan Vickers machine. Such a simplification is almost revolutionary, and since to this simplification is added a reduction in the sampling error, only hope that the machines will soon go into production. Cell counts may be unnecessary in diagnosis, but are very useful, particularly in assessing the results of treatment, and in some problems which are more general than medical, such as the supervision of X-ray radium workers.

London N 10

GEORGE DISCOMBE

PERIPHERAL URÆMIA DUE TO ACUTE UPPER-NEPHRON NEPHROSIS

SIR,—The acute upper nephron nephrosis described in our issue of July 22 by Dr Govan and Dr MacGillivray recalls some histological findings seen occasionally in cases of "crush syndrome" during the war. It was established in those particular instances that the disease had been given to induce diuresis, and in view of the close similarity to the renal appearances after sucrose administration we dismissed such findings as coincidental. It tended to mask more important renal pathological changes. In two of the three Glasgow cases it is recorded that sucrose had been given, and it seems possible that acute upper nephron nephrosis is, in fact, merely a sucrose effect. It would be interesting to know how certainly sucrose administration could be excluded in the first of three cases.

Canadian Red Cross Memorial
Hospital, Taplow Bucks

E G L BYWATERS

SIR,—Dr Govan and Dr MacGillivray (July 22) describe an "upper nephron nephrosis" in addition to the accepted "lower nephron nephrosis" of acute renal failure due to a variety of causes. From their very full case records, however, it seems that this new syndrome included the effect of treatment. Firstly, all three cases were extremely shocked, secondly, two at least received "intravenous" fluid. Of these two factors, one would lower the blood pressure, and the other, with its antidiuretic effect, would tend to lower the rate of urine formation. Thirdly, all three cases were apparently overhydrated, they exhibited, not uræmic symptoms necessarily, but those of water intoxication, this is particularly suggested by the finding of oedema of the brain in the first case.

Thus the pathological picture was made up as follows: (1) shock, hæmorrhage, and the administration of intravenous fluid, leading to hepatic and renal anoxia with subsequent deleterious effects, and (2) overhydration. Hence water imbalance resulting in—to take one of the most relevant instances—oedema of the cells of the convoluted tubules, which having extracted fluid from the surrounding fluid possibly salt from the glomerular filtrate were unable

to pass the fluid by osmosis to an already overloaded circulation.

It is now generally accepted that, after treatment of the shock and blood loss, fluid replacement should be regulated according to urinary output plus the invisible loss—i.e., about 1000 ml daily—and including, of course, salt replacement where vomiting occurs. In this way water intoxication can be avoided and the kidneys given a fair chance to recover, helped possibly by the sundry other means at our disposal.

Peterborough

D W BRACEY

SIGNIFICANCE OF THE DISCOVERY OF THE EFFECTS OF CORTISONE

SIR,—In his letter of Aug 12 Dr Eastwood states that Professor Pickering, in his lecture published in your issue of July 15, "did a public service by his strictures on the psychosomatic theory of disease." It is my opinion that both he and Professor Pickering have done a public service in illustrating how widespread is the failure in the medical profession to understand what is meant by psychosomatic medicine, and how great is the need to replace prevailing fantastic notions on the subject by more accurate comprehension.

The term "psychosomatic medicine" refers primarily to a method of examination. It signifies that a patient is examined physically (with all this implies) and then psychologically (with all this implies). When a physical approach is used in investigation we get one set of findings, and when a psychological approach is used we get another set of findings. Each set of findings (or both) may provide us with guidance for action—that is, for practical therapeutics. The omission of the psychosomatic approach is the reason for many unnecessary failures in medical practice and for the prolongation of much invalidism. The term "psychosomatic" medicine refers also to the body of knowledge which has been, and is being, acquired by adopting this combined method of approach and acting in terms of that knowledge.

There is no such thing as a psychosomatic disease. It is, however, useful, especially perhaps to the epidemiologist, to adopt the concept of a "psychosomatic affection" in relation to those disease labels that cover cases in which the psychosomatic method of examination and treatment often proves highly relevant. These disease labels include not only the various forms of neurosis but also many organic diseases, including peptic ulcer, fibrositis, rheumatoid arthritis, and chronic bronchitis—to name only a few. From the standpoint of systematic medicine, these psychosomatic affections are distinguished from diseases in other broad ætiological categories (e.g., the infectious diseases) by certain peculiarities from whose formulation the concept of a psychosomatic affection has been derived. They include the following:

- (1) Examination of patients diagnosed with such disease labels shows a significant association between the emergence or recurrence of the bodily disturbance and the emotionally upsetting events or situations.
- (2) Persons with well marked obsessional tendencies seem to be particularly liable to develop psychosomatic organic disease.
- (3) There is a pronounced disproportion in the sex incidence of these disorders.
- (4) The person who develops one psychosomatic affection is liable to suffer either from a recurrence of that disease or from substituting affections which take its place.
- (5) There is a substantially higher incidence of such illnesses in parents and siblings of the patients than in the general population.
- (6) The course of the illness is phasic with periods of crudescence, intermission, and recurrence.
- (7) The incidence and prevalence of the psychosomatic affections is related to changes in the communal environment considered psychologically and socially.

It will be noted that the concept of a psychosomatic affection bears certain resemblances to Selye's concept of diseases of adaptation or stress diseases. In Western

civilisation the commonest forms of stress, however, are not those of extremes of heat or cold or malnutrition or fatigue but emotional, and these stresses are attended by dysfunction of the autonomic and endocrine mechanisms which may take a great variety of forms

Far from exposing the fallacies of "the psychosomatic theory of disease" (whatever that is) the discovery of the effects of 'Cortisone' on rheumatoid arthritis and other diseases is entirely in keeping with the knowledge of these affections gained by the application of the psychosomatic method

Glasgow

J L HALLIDAY

ISOLATION OF POLIOMYELITIS CASES

SIR—I suggest that the time has come to reconsider our policy with regard to the isolation of cases of poliomyelitis. It is now generally accepted that the great majority of cases are undiagnosed but are just as capable of spreading the disease as the recognised cases with meningeal inflammation or paralysis

Thus, recently I saw a child with meningeal signs and a pleocytosis in the cerebrospinal fluid, within three days she was perfectly well. There was a history that her brother had had an exactly similar illness two weeks before, and her sister the day before, but neither had undergone lumbar puncture and both had recovered. As both these patients were still at home I could conceive no advantage from isolating my patient for three weeks; nevertheless this was done, with the attendant wastage of beds and nursing staff

Even worse, perhaps, was the case of a district nurse who assisted a practitioner with the lumbar puncture in a case of poliomyelitis. Because she had been in contact, she was instructed to cease her duties for three weeks. Surely by now we should allow reason rather than prejudice to dictate our actions, and realise that isolation of poliomyelitis cases serves no useful purpose in preventing the spread of the disease

Exeter

N S ALCOCK

ACQUIRED SENSITIVITY TO SODIUM P.A.S.

SIR,—Dr Cuthbert's article of Aug 5 prompts us to send this note on a case very similar to though less severe than that reported by him

The patient was a single woman, aged 22, who had tuberculous disease with cavitation in the upper lobes of both lungs. She was treated with a long period of bed rest, and on Aug 8, 1949 a course of sodium P.A.S. (20 g a day in divided doses for 6 days a week) was started. No nausea or vomiting was noticed in the first weeks of the treatment

On Aug 30 the patient's temperature rose suddenly to 104°F, and she complained of stiffness of the neck. The cervical glands were found to be enlarged and tender, and the body was covered by a fine red macular rash. During the next few days the temperature varied from 99° to 102°F, the rash became more pronounced and was intensely irritating

On Sept 5, in addition to the macular rash, which at all times respected the flexor aspects of the knee and elbow, numerous urticarial weals were seen on the body. On this day jaundice was first manifest, and bile was found in the urine. At no time was there any albuminuria

By Sept 10, the jaundice was no longer apparent, the rash had faded, and a fine desquamation had started

On Sept 12, the patient was afebrile and the skin had cleared. There was no previous history of sensitivity to salicylates. There were no known cases of epidemic jaundice in the neighbourhood at this time. The agglutination reactions for *Leptospira icterohaemorrhagiae* and *L. canicola* were negative in all dilutions. Blood culture taken at the height of the fever was sterile. The total white cell count was 8600 per cmm with an eosinophilia of 9%

The administration of sodium P.A.S. was stopped on the first appearance of the rash. The patient was given ephedrine hydrochloride gr 1½ b.i.d. for two days, and thereafter 'Benadryl' was exhibited until the rash began to fade

Obituary

WALTER JAMES DILLING

M B ABERD

Dr W J Dilling, professor of pharmacology general therapeutics at Liverpool University many years dean of the medical faculty, died on Aug 1 while on holiday at Coniston

Born in 1886, in Aberdeen, he was educated at Gordon's College and Aberdeen University, graduated M.B. with honours in 1907 at the possible age of 21. After holding a Carnegie scholarship in physiology at Aberdeen he was appointed assistant to Robert, who was then professor of pharmacology and physiological chemistry at Rostock. The following year Dilling returned to Aberdeen as lecturer in pharmacology, and he held this post until his appointment in 1914 to the newly established Pollok lecture ship in materia medica and pharmacology at Glasgow. His work there was interrupted in 1915 by war service, and in 1920, soon after his return to civilian life, he went to Liverpool as lecturer in pharmacology and therapeutics, later becoming professor in these subjects

Dilling acquired a great reputation by his textbooks. At a very early age he edited Bruce's *Textbook of Materia Medica* and he later became the sole contributor. Bruce and Dilling was well known to a generation of medical students as a sound and complete textbook on the subjects of pharmacology, materia medica, and general therapeutics, and was so popular that it reached the 18th edition in 1944. His volume on *Dental Materia Medica, Pharmacology and Therapeutics*, written in association with S Hallam, reached its third edition 1946

A colleague on the General Medical Council, to Dilling was nominated in 1938, writes "Prof. Dilling's reputation lay more in his great skill as a writer of books than in his contributions to experimental pharmacology. His encyclopaedic knowledge of the subject was of immense benefit to the various public bodies with which he was associated. As Privy Council representative on the council of the Pharmaceutical Society he did splendid work, and it was hoped when he was elected to the chairmanship of the Pharmacopoeia Committee of the General Medical Council in May last that he would have rendered the same great service in a new sphere. Those who know most of his work and worth will appreciate what the medical profession have lost in this great expert in the use of drugs"

From 1922 to 1933 and again during the difficult years of the late war he was dean of the medical faculty and he was also twice a member of the university council. His period of deanship was comparatively tranquil. At heart he was a peacemaker. He regarded it as an opportunity for studying the needs of his students and for further self-sacrifice in their interests. Thus as the number of his students doubled, he doubled his lecture and he provided a corner in his small laboratory where the musically minded could meet in the lunch hour. Music was always one of his chief interests, and he founded the Musical Society and linked the students with Philharmonic concerts. He encouraged Liverpool to rebuild the blitzed concert hall and he became chairman of the Philharmonic Society at the opening of the new building

During the late war Dilling, with his friend Mr A A Gemmell, organised the student stretcher bearers who met the ambulance trains and unloaded them. The dreary midnight watches and alarms often made the work heavy for the young students who included his own daughters, but it was cheerfully performed and his leadership. Ill health followed these years of strain and periods of physical rest became necessary to him, but he continued to edit his books, delight his visitors and start work again as soon as possible to the astonishment of his colleagues and

writes 'Dilling was a likeable man, approachable, knowledgeable in subjects far removed from urology. A true professor unostentatious and deeply imbued with the spirit of the Scots domine, proud of his pupils and keen to see them get just reward. He endeared himself to the students by his colleagues and their children, for amidst countless files on drugs, their uses and abuses, in his home or in the university there was always something to appeal to the curiosity of all ages—the insects under the bell jar, the idols from Egypt where flint axes of the Stone Age could be found, bees most likely to be struck by lightning, the moths and the butterflies and how to mount them, the fashions of the eighteenth century, the colour process and painting of flowers, the meaning of girdles and the value of sixpence in a secondhand bookshop. Not consultations in his office concerned pharmacology, they were always of value, for the information would be accurate, often spontaneous, more often asked and confirmed by several pages in his own writing with quotations to support or correct his own."

1914 Professor Dilling married Miss Vida Ducat and survives him with two daughters

BERNARD JOSEPH WARD

F.R.C.S.

Dr Bernard Ward, formerly senior surgeon of the Elizabeth Hospital, Birmingham died at his home at Shelsley Beauchamp on June 30, at the age of 61.

He was the son of the late Dr Joseph Ward, who practised many years in Birmingham; he was a student at Birmingham Medical School and the London Hospital, qualifying in 1902, he held resident posts at the Elizabeth Hospital Birmingham, and in London at St. Peter's Hospital for Stone. In 1905 he took his F.R.C.S. and settled in consultant practice in Birmingham. A few years later he was appointed assistant surgeon to Queen's Hospital. He also joined the staff of the Children's Hospital. He served the medical school as tutor and examiner in surgery. He achieved his greatest reputation in urology; he was president of the Association of Urologists of the Royal Society of Medicine and when he died was vice president of the British Association of Urological Surgeons. To commemorate this office he presented the Ward medal which is offered to outstanding work in urology.

A colleague writes 'Although Ward hated publicity, he earned for himself an international reputation. However, it will be by his hospital colleagues and assistants that he will be most missed. To those who met him usually he sometimes appeared brusque and even short-tempered, this outer roughness shielded a nature of great gentleness and kindness.

He sometimes appeared to be vague about his patients and occasionally even about his staff. One quickly learnt that this was a cloak, covering an accurate knowledge of their illnesses, their personalities, and their difficulties which was assumed so that his assistants could do their best without any interference from him. He always spotted the omission of any essential at once and brought it to our notice by some devious method that could make us think that we had thought of it ourselves. It was this generous side of his nature that turned those who worked for him into his devoted admirers.

As a clinician he was first-rate, out of his vast experience he seemed to have developed an instinct for the abnormal, which depended on acute observation and an ability to see fundamentals unobscured by complications. This lucidity was characteristic of his whole life—operating, his thoughts and his actions. His clarity of mind made it difficult for him to tolerate fools, and though he learnt to control his feelings we learned that he was answer silent usually meant someone had said something silly and sent us away to reflect upon it. Of his many kindnesses few knew anything. He would take no less trouble to disguise them and any attempt at thanks was usually met with an almost shamefaced smile.

Mr Ward leaves a widow formerly Miss Olga Bates, Edgbaston and a daughter and two sons

Notes and News

REPORT ON TOXICITY TESTS

In his admirable study¹ of the methods of testing the toxicity of drugs Dr W. L. M. Perry has tried not to overburden the reader with statistical theory. His aim has been to help those whose mathematics is too weak to cope with detailed discussions of this subject and he has succeeded. He first examines assay by quantal (all-or none) response and then assay by graded response emphasising that each test should be self-contained should contain no arbitrary assumptions and should provide an estimate of its own error. He goes on to evaluate the current test designs on this principle. In a last section he describes toxicity tests depending on the measurement of survival time, which have the great advantage of needing fewer animals than those based on quantal response.

ION-EXCHANGE RESINS

The synthetic resins, whose medical applications were discussed in a leading article on Aug 12 (p. 358), are mainly being used in two forms: (1) anion-exchange resins for removing acids, such as gastric HCl from solutions; and (2) cation-exchange resins for controlling the concentration of sodium chloride in solutions particularly in the intestine or in milk and other foods before ingestion. The Permutit Co. Ltd. inform us that they can supply both types of resin for experimental purposes. Their anion-exchange resin, 'De Acidite E,' has an acid absorption capacity of 4 meq per (dry) gramme and is supplied in coarse granules which may require crushing before use. Their cation-exchange resin, 'Zeo Karb 225,' has a hydrogen ion exchange value of 2.5 meq per (dry) gramme and is also supplied in granules. Neither of these resins seems to be at all toxic to man.

The apparatus for purifying sea water, mentioned in the same article, was described by Akeroyd et al.² nearly five years ago.

THE ARTIST AND THE ID

'OPEN wide the mind's cage-door.' This is Miss Joanna Field's aim and in her third book—'On Not Being Able to Paint'—she sets out to show how it can be done by 'free drawing.' She draws she says, without any conscious intention to draw something. Applying psychoanalytical principles to the results she comes to conclusions about herself, about the nature of art and about 'living and education.' What she discovers about herself is not, of course of general application, but shows she has got a technique for reaching that inner life which so many of us succeed in concealing from ourselves. But it is not easy to grasp just what she is saying about art. It is an explanation on psychoanalytical lines of the artists' heightened sensibility and intensity of feeling. About living and education her point is that we err in overvaluing the intellect and undervaluing the emotions. The book contains material which should be of value to the psychotherapist, but one cannot help regretting that Miss Field has not written it with a more conscious intention to say what she means.

Society of Apothecaries of London

At a recent meeting of the Court of Assistants, with Mr Duncan Fitzwilliams, the master, in the chair, Dr Frank Howitt was elected master from Aug 23. Dr G Roche Lynch and Sir Wilson Jameson were elected wardens. The honorary diploma of mastery of midwifery was conferred upon Dr Hugh F Powell.

The following were clothed with the livery of the society: H A Treble, Sir Lionel Whitby, E Grey Turner, P C Alexander, R M Maher, G P West, Lord Amulree, A J Wrigley, B H Hogben, Rev M F Foxell, G F Keatinge, Guy Blackburn.

The following were admitted to the freedom of the society by redemption:

B E Schlesinger, P L Blaxter, Sir Arnold Stott, F P Lee Lander, A M Hutton, P J Helliwell, J J Keever, Donough O'Brien, T S Leedham, G A Mason, J W McLaren, R Bodley Scott, J F Dow, Terence East, N L M. MacManus.

The following were sworn in as examiners: Guy Blackburn (surgery), H C Stewart (materia medica and pharmacology), and R V Lloyd (practical section of the assistant's examination).

The following were granted the diploma of L.M.S.S.A. upon examination:

P A Van Der Merwe, A H R Hewett, Clarke W B Wright, P F E Kann, M K Mangan, M el K A Tarshouby, L Tippet, C E Law, A J Rowe, W C Snook, H C Killey, N L Rowe, D G Bluet, D L Hadley, T G Scott, R A Davidson, W H Bexon, A Gordon, P H I Parsons, B Kay, R N Pearson, J M Hayman, G T Gould, R E Hazell.

Edinburgh Post-Graduate Board for Medicine

On Friday, Sept 8, at 4.30 P.M., in the anatomy lecture-theatre of the university, Dr W D M Paton will speak on the Paralysis of Autonomic Ganglia.

Exhibition of Photography at Manchester

The International Exhibition of Medical Photography, sponsored by the Royal Photographic Society, which was recently shown in London, will be in Manchester from Oct 9 to 14, in the museum of the Royal Infirmary. The exhibition will be officially opened at 11.30 A.M. on Saturday, Oct 7, by Mr R L Newell, dean of postgraduate medical studies in the University of Manchester.

U.S. Need of Service Doctors

In the United States all the Services are short of doctors, and the department of defence is seeking authority to call up doctors under 46 years of age even though they are not on the Reserves. Mr Louis Johnson, secretary of defence, has said that unless such action is taken "substantial numbers" of doctors of all military grades who served long tours of duty in the late war are likely to be called up. The *New York Times* (Aug 26) reports that the department's proposals are aimed particularly at the thousands of doctors who received their medical training in the late war at the expense of the Army or Navy but are now under no obligation to serve. Under a Bill sponsored by the defence department, the first doctors to be called up would include this group, and also those whose service was deferred during the late war for them to continue their education and those who had done less than 90 days' active duty in the Armed Forces. The Bill would also apply to dentists.

Health Committee of Brussels Treaty Powers

The sixth session of this committee is to be held in St Andrews House, Edinburgh, from Sept 7 to 9, under the chairmanship of Sir Andrew Davidson, chief medical officer of the Department of Health for Scotland. The committee was set up by the governments of Belgium, France, Luxembourg, the Netherlands and the United Kingdom to look into the development on corresponding lines of health services in these countries and is composed of experts of the five countries in the field of public health. Some of the subjects to be considered at this session are the comparison of medical education in the five countries, the exchange of medical and auxiliary medical personnel, the protection in war time of the civil population from a health point of view, and the standardisation of blood transfusion apparatus. The following will represent the United Kingdom at Edinburgh: Mr R G Forrest, assistant secretary, Department of Health for Scotland; Dr R J Peters, deputy chief medical officer, Department of Health for Scotland; Mr W H Boucher, assistant secretary, Ministry of Health; Dr N M Goodman, senior medical officer, Ministry of Health; and Dr J Boyd, chief medical officer of the ministry of health and local government, Belfast.

Westminster Medical School

On Monday, Oct 2, at 3 P.M., at Church House, Smith Street, London, S.W.1, Sir Cecil Wakeley will deliver the inaugural address for the next session.

American College of Chest Physicians

This college offers each year a prize of \$250 for the original contribution, preferably by a young man, on any phase relating to chest disease. The prize is contested by contestants living in other countries as well as in the States. Further particulars may be had from the office of the college, 500, North Dearborn Street, Chicago, Ill. The closing date for entries for the 1951 April 1, 1951.

Nuffield Fellowships for Ceylon, India, and Pakistan

The Nuffield Foundation is extending the travelling fellowships scheme—already in operation in Australia, Canada, South Africa, and New Zealand—to new Dominions of Ceylon, India and Pakistan. Fellows will be appointed by the foundation on the recommendation of an advisory committee in each Dominion. Each fellow will be of one year's duration, and—according to whether the holder is married or single—will be of value between £800 and £890. Travelling expenses to and from the Kingdom will also be paid. In the first year of the fellowships will be awarded: Ceylon, one (in medicine); India, five (two in medical sciences); Pakistan, three (not yet selected).

Prof W W C Nixon is leaving this month for a tour, sponsored by the Rockefeller Foundation, of teaching centres in the United States and Canada. On his return he is delivering the DeLee lecture, at the Chicago L. Hospital, on Uterine Action.

CORRIGENDUM Association of Clinical Pathologists: the report of the meeting of the association (*Lancet* Sept 2, p. 254) the title of Dr Norah Schuster's presidential address was Nec Silet Mors. Leonardo da Vinci, at the time of his traditional visit to the medical school at Milan, could have been more than 60 years of age.

the past four months THE LANCET has been added under difficulties caused by a dispute in the g industry in London. These difficulties have duced it temporarily to vestigial proportions and ch regret the inconvenience thus caused to readers, utions, and advertisers. On the hospital and vacancies which have been tribulated, our tment Manager will gladly give fuller information nding applicants.

Potassium Lack

climicians respect for the electrolytes of the body grown slowly in the hundred years since CLAUDE ARD developed his concept of the *milieu intérieur*. SIDNEY RINGIER in his classical experiments at ersity College, London demonstrated the vital ce between sodium potassium, and calcium salts e fluids bathing the tissue cells. At first the investi- r's attention was focused on sodium, because of its onderance in the extracellular fluids and because ating diarrhoea and vomiting led mainly to a loss of ion. Moreover the success of sodium chloride sions in cholera &c, coupled with the comforting wledge that the cells are full of potassium and the ttening effects of intravenous injections of potassium, de clinicians reluctant to believe in lack of potassium cause of trouble, except in very rare conditions such familial periodic paralysis. t is largely owing to the patient's skill of DARROW and associates¹ in New York that the wider significance potassium in medicine and surgery is beginning to be ogised. By analysing animal tissues and studying salt balance of infants with diarrhoea, they showed t large amounts of potassium had to be absorbed and s into the muscles before these infants could agum be sed as normal. Many other causes of potassium icency have since been established, including burns d other trauma, hæmorrhage, and diabetic coma, toperative vomiting, pyloric stenosis, and intestinal struction. Though WILKINSON and his associates at anburgh² report an increase in potassium excretion in first few days of normal recovery from operation uthal gastrectomy), it is in complicated surgical cases t lack of potassium should particularly be borne in nd, NADLER and his colleagues³ suspect hypokalemia any case of intestinal obstruction with protracted ating, and a serious lack is probable if the patient been treated by gastric suction or with infusions of um chloride solution only. The typical signs are ed and feeble muscles, low blood pressure with a unding pulse, and a loud systolic precordial murmur e diagnosis can be proved by finding a serum potassium el below about 14 mg per 100 mL, but even with a me photometer, to speed up the estimations the lent nod of a biochemical department's synapses is often tressingly long. In practice therefore, it may be re convenient to rely on the rougher but reliable adance of the electrocardiogram, which shows a

prolonged Q-T interval and lowering or inversion of the T wave. In treatment potassium chloride or citrate can be given by mouth if this is practicable in doses of 2 g half hourly, 100-1000 ml of a 1.14% solution of the chloride can be injected intravenously, or 500 ml of this solution with an equal amount of sodium chloride can be given by hypodermoclysis. The only absolute contra-indication is poorly functioning kidneys but potassium salts are not a remedy to be lightly prescribed on the off chance of doing good.

Many clinicians will be satisfied to recognise and cure their cases of potassium deficiency: few of them are interested at the moment in the factors which control the physiological levels of potassium and of sodium in the cells or in the internal environment. Yet these are the problems which investigators are facing today. The old idea of the cell membrane, impermeable to the ions is giving place to a much more dynamic conception based on the expenditure of energy by the cell. The equilibrium between ions in the cells and in their environment is a matter of cell metabolism and is modified by physiological activity, by the pH of the cell's surroundings and by hormones such as deoxycortone. Ions undoubtedly pass freely into and out of respiring cells, often against a steep diffusion gradient⁴, and water also may be forced out of an active cell so that the osmotic pressure inside it is steadily maintained above that of its surroundings⁵.

Annotations

CREMATION

As the result of submissions made by the Cremation Council of Great Britain the Home Secretary in 1947 set up an inter-departmental committee with Mr H. A. Strutt as chairman, to review the regulations made under the Cremation Act of 1902. Its report⁶ shows that the number of cremations in this country rose from 1796 in 1920 to 79 807 last year. Cremation authorities however have long been anxious to modify the legal and other handicaps placed upon cremation—handicaps framed at a time when cremation was not only unpopular but to some extent suspect. The committee recommends that the statutory declaration required in conjunction with the form of application should be dispensed with—an easement long desired. It thinks that the certificate on form B (that of the medical attendant) should be in more detail if the coroner has been consulted, or if there has been a necropsy or an operation within a year before death, these facts should be stated. Its proposal that form C (the confirmatory certificate) should be retained runs counter to the hopes of the Cremation Council of Great Britain, the Society of Medical Officers of Health and the Association of Municipal Corporations—bodies which considered this form a serious deterrent to the practice of cremation partly because of the complication introduced into the arrangements and partly because of the expense entailed. In respect of the last point however it is suggested that the Secretary of State should be empowered to lay down maximum charges for both medical certificates.

Speaking generally, the recommendations tend to eliminate the penalisation of cremation as against earth burial. This will help to make the former an easier and more efficient public service than it is at present.

CORTISONE AND ACTH

THE brilliant demonstration by Hench and his colleagues in the Mayo Clinic of the effects of 'Cortisone' or ACTH in rheumatoid arthritis has been developed so swiftly in the U.S.A. that even the expert cannot be sure that his information is up to date. With the purpose of bringing together prevailing knowledge two conferences were held last autumn in the U.S.A. and the proceedings have now been published in *Arthritis*. The reports give a good idea of the wide scope of the work done in six months or so. These substances have been tried in the following array of disorders: collagen diseases (rheumatic fever, rheumatoid arthritis, disseminated lupus erythematosus, dermatomyositis, and scleroderma), overt allergies (atopic dermatitis, drug sensitisation, hay fever, asthma, nasal polyps), glomerulonephritis and nephritic syndrome, gout, neoplastic diseases (carcinoma, Hodgkin's disease, chronic lymphatic and myeloid leukaemia and acute leukaemia), specific infectious diseases (pneumococcal and virus pneumonia, tuberculosis, poliomyelitis, chronic infectious hepatitis, and herpes), cirrhosis of the liver, ulcerative colitis, pemphigus, hyperthyroidism, diseases of the central nervous system and of muscle (myasthenia gravis, amyotrophic lateral sclerosis, muscular dystrophies, disseminated sclerosis, and various psychoses), and congenital hypoglycaemia.

This form of therapy is not hazard free. Thus ACTH may give rise to defects in wound granulation, a rise in blood pressure, possibly endangering life in hyperpiesics, and a modified Cushing's syndrome characterised by 'moon face', acne and even hyperglycaemia. Mental changes have also been noted, often the patient has no more than an exaggerated sense of well being, but sometimes the picture is more serious. One of Spies's³ patients, for example, developed hallucinations, and agitated depression has been reported. Hofer and Glaser⁴ have lately recorded significant electroencephalographic changes in 13 out of 15 patients treated, with psychiatric symptoms in 10.

SERVICE WITH THE FORCES

LAST week's announcement that the Government are to seek Parliamentary sanction to prolong the period of compulsory national service from 18 months to 2 years will be particularly unwelcome to medical students, who from 1952 onwards may also have to spend a year in hospital appointments after qualifying before their names can appear on the Medical Register. The longer period of service will underline the shortage of specialists in the Army⁵, and it cannot offset the threatened serious dearth of general duty medical officers, due to the large proportion of ex-Servicemen among the newly qualified. In one way, however, the Forces will gain a better medical service, as anyone who has served with the R.A.M.C. will know it takes some 18 months to become a fully competent regimental medical officer, and now the Army will be retaining its doctors for an extra 6 months when they really know the ropes. The all round increase in pay after the first 18 months of service, also announced for all the Forces last week, does not apply to doctors, dentists and some others. The negotiations on this subject, which the British Medical Association has been conducting have been overtaken by the latest developments, but an announcement is expected very shortly.

PERIL IN THE POT

Two sorts of infection beset man—those that cannot be prevented and those that can. On the whole the first group have treated this generation gently and with improved preventive measures there has been gradual transfer from the inevitable to the preventable group. Food poisoning is now certainly one of the preventable infections and yet it is steadily becoming more prevalent: last year over 800 outbreaks were reported in England and Wales and the total seems likely to be more than doubled in 1950. The main causes of the increase—the growing popularity of communal feeding and of made up dishes—are as well known as the organisms which make us ill, and if the counter actions still fall short

of the need this is probably because the illness is so seldom disabling for more than a few days. At a meeting convened by the Central Council for Health in London last week, Miss Betty Hobbs wondered if modern practice of building the small kitchen on south side of the house, often with a water-bomb kept at full blast, might not lie at the root of some outbreaks. This reversal of the previous tendency to place the kitchen in the basement and store the food in a cellar no doubt reflects a consideration for the wife's comfort which was denied to domestic servants. It may also be based on the assumption that even to have a refrigerator, which is not yet true in the U.S.A. and though it has nearly been attained in the U.S.A. and No-one would advocate a return to basement kitchens, it might not be a bad thing to ensure that landladies on the chiller northern aspect and to give more cheap household methods of keeping food cool and from flies. The risks of food poisoning may never be removed—sooner or later someone will fall in the routine—but let us at least be rid of outbreaks not to human fallibility.

Dr G. S. GRAHAM SMITH, F.R.S., co-editor of the *Journal of Hygiene* and emeritus reader in preventive medicine at the University, died on Aug. 30, aged 75.

Dr ERNST LOEWENSTEIN, originator of the culture technique that bears his name, died in San Francisco on Aug. 29.

In England Now

He comes every week, but this morning even the shadow of his normal self, and his buff overcoat was in lump folds. On examination I found the cause in a superior part of the anterior editorial column.

Next week he'll probably be brought in flat out. You have no doubt about the ultimate prognosis. You reach the age of 127 without going through a few lean times and these tough old timers fill out again quickly.

News

In the week ended Aug. 26, notifications of poliomyelitis in England and Wales totalled 589 (paralytic 369, non-paralytic 220). Totals for the four previous weeks from that ended July 24 that ended Aug. 19, were 306, 367, 393, and 550.

Over 1300 private chemists in Scotland have given three months' notice of intention to withdraw from the National Health Service. They object to the 8% cut in their earnings lately imposed by the Secretary of State without arbitration.

The North West Metropolitan Regional Hospital Board asked management committees to aim at a 90% occupation of hospital beds.

At an inquest in Birkenhead on Aug. 31 a verdict of accidental death was returned on a 15-month-old girl who died after swallowing four tablets of an anti-histamine drug. Such preparations have lately been added to part I of the Poisons List and the first-aid instructions.

The dispute on salaries in the public health service is to be before an industrial court on Oct. 9.

Prof. A. Levland Robinson will give the William Fletcher Shaw lecture at the Royal College of Obstetricians and Gynaecologists, on Sept. 29 at 2.30 P.M. He is to speak on 'Evolution of the Gynaecologist'.

Prof. Lillian Panson, vice-chancellor of London University, will deliver an inaugural address to the Royal Free Hospital of Medicine on Friday, Sept. 29 at 3 P.M. at B.M.A. House.

Sir Lionel Whitby will give the inaugural address at the College Hospital Medical School on Friday, Sept. 29 at 3 P.M.

The first success in an international search for group O with the rare rhesus homozygous pattern cde/cde (Rh⁻) was reported on Sept. 1 from Bristol. The blood was from a patient in St. George's Hospital, London.

The first stage of the new Australian medical service decision, Sir Earle Page, F.R.C.S. (see *Lancet* Aug. 19 p. 303) was laid on Sept. 4 when 135 costly drugs were made available on charge on presentation of a doctor's prescription.

Mr. T. C. Denston, F.R.C.S., has been appointed secretary of the British Pharmacopoeia Commission in succession to Dr. Hampshire, who will retire on Oct. 3.

The first International Congress of Cardiology opened its last Sunday under the presidency of Sir John Parkinson, nearly 1000 members from 32 countries.

The fifth International Congress of Microbiologists, held in Rio de Janeiro with 697 members from 37 countries, decided that it is at present unwise to use a scientific nomenclature.

we go to press it seems likely that this journal will see its usual appearance next week. As soon as our conditions become normal we shall do our best to make up for the delays in publication during the few months. Meanwhile we are grateful to our contributors and advertisers for the forbearance every one of them has shown, and we must also (though with mixed feelings) thank those readers who have expressed themselves as wholly satisfied with the few we have been able to offer.

After Gastrectomy

ALTHOUGH the results of gastrectomy vary, it would probably be fair to say that 95% of patients survive the operation, 75% are relieved of their old symptoms without acquiring new ones that bother them, and 20% have further symptoms due either to recurrent ulceration (4%) or to disturbance of alimentary function. Occasionally the functional disturbance is severe. Thus a doctor who wrote in our Disabilities series said that he had known about the attacks of extreme lassitude which were to follow his gastrectomy he would rather have kept his ulcer and borne its pain.¹ MUIR² finds that, next to the much debated dumping syndrome, the commonest postoperative trouble is failure to gain weight. Six months after gastrectomy, more than 40% of the 86 patients he investigated had lost half a stone of their preoperative weight, and some had lost much more. Often it was clear that this loss was due to "dumping", the patients ate small meals to avoid discomfort. But in 7 cases there was no obvious reason, and 5 of these were found to have steatorrhoea. Actually, it is remarkable how many patients after gastrectomy "go off" fats, often finding that milk, especially if creamy, gives them diarrhoea. The causes of their disordered fat absorption seem to be much the same as those of dumping symptoms. The small intestine, faced with a rush of unpeptonised food, must attempt a hurried job of digestion and absorption for which it was not designed—it normally has its material soaked out in small quantities. Moreover, the popular Billroth II type of operation may interfere with the free flow of bile and pancreatic juice. Its most usual variant requires the attachment of the afferent loop to the lesser curvature of the gastric stump, and at this point the afferent loop is kinked and may become partly obstructed. Then, in the words of MIMPRISS and BIRT,³ "the meal may empty rapidly down the jejunum, although the bile and pancreatic juice are detained at the upper end of the intestinal tract." The effect of this on fat absorption is obvious, and its probability is underlined by those patients whose dumping syndrome is accompanied by vomiting of bilious fluid, unminged with food, shortly after a meal. That gastrectomy may have yet more subtle effects on the biliary system (and therefore on fat absorption) is suggested by MAJOR and SUREN's⁴ observation on the appearance of gall stones after gastric resection. As MUIR remarks, further investigation of abnormalities in fat metabolism after gastrectomy is obviously needed.

While this evidence is accumulating, certain provisional measures seem likely to help. Most surgeons probably believe that in the Billroth II type of operation the afferent loop should still be attached to the lesser curvature of the gastric stump, so as to discourage filling of this loop and hence reduce one cause of dumping. But the higher the gastrectomy with this anastomosis the more acute will be the kinking of the afferent loop and the greater the likelihood of its retaining bile and pancreatic juice, and there are therefore advantages in a gastrectomy less radical than a subtotal removal. A further reason for preferring a two thirds excision of the stomach to a more extensive ablation is that the gastric stump holds more food. On the debit side must be reckoned the higher incidence of recurrent stomal or jejunal ulceration. The late HEDLEY VISICK⁵ reduced this complication to nil by his very radical operation, but his paper did not give details of the frequency and seriousness of postoperative dumping and weight loss, nor would his methods necessarily be so successful in the hands of surgeons without his exceptional skill and enthusiasm. The Billroth I technique of gastrectomy, in which the gastric stump is anastomosed to the duodenum, should avoid some of the troubles enumerated, because it does not disturb the flow of bile and because the capacity of the stomach cannot be reduced beyond a certain point if it is to be anastomosed to the duodenum. Unfortunately this technique is difficult and sometimes impossible with duodenal ulceration, but it would be interesting to have a follow up, as detailed as MUIR's, on a series of Billroth I operations, and to know how frequent are dumping and inability to maintain weight.

Gastrectomy is now done so often that its failures demand careful study. As HOSFORD⁶ said when reviewing his gastrectomies, the truth is very elusive, and its capture here needs prodigious labours.

Annotations

PENICILLIN RHEUMATISM, AND NEPHRITIS

WE recently concluded that penicillin can usefully be given to rheumatic subjects to prevent recurrent attacks of streptococcal throat infection, but there is less certainty about its power to reduce the likelihood of rheumatic sequelae when it is given to patients whose throats are already infected. Jersild's observations on glomerulonephritis were more encouraging for he found no renal damage in 1000 cases of scarlet fever treated with penicillin.⁷

Weinstein et al.⁸ doubt whether penicillin given during streptococcal infection will prevent either rheumatic fever or nephritis. In their uncontrolled series of 187 cases of scarlet fever all treated with penicillin (about three quarters of them within two days of the onset) rheumatic fever ensued in 12 (7.2%) and nephritis in 6 (3.6%). On the other hand, they think that in penicillin treated patients both rheumatic fever and nephritis may take an attenuated or cryptic form—which may pass unnoticed in the absence of repeated laboratory investigations including electrocardiographic and urinary studies. Of their 12 rheumatic patients only 5 had an appreciable rise in temperature when the rheumatic process

seemed most active, in the other 7 "there was complete lack of febrile response at times when arthralgias were present, new murmurs were appearing and the electrocardiogram was showing progressive changes". In children, they insist the joint disorder manifest itself less commonly as a polyarthritides than as an arthralgia, which may not be migratory and may affect only one joint. In only 1 of the 12 cases was the erythrocyte sedimentation rate increased while the rheumatic process was thought to be active, and serological studies yielded inconsistent evidence of antibody formation. Of the 6 patients with nephritis, only 1 had clinical manifestations, only 3 became febrile, and only 3 had an increased E.S.R., and in not a single case was there serological evidence of antibody formation. If as this paper suggests, the more serious complications of streptococcal infection may be masked rather than prevented by penicillin, children receiving such treatment will need more careful watching than most of them now receive.

CORTISONE AND INSULIN

A RECENT preliminary report¹ suggests that insulin has a 'Cortisone' sparing action and that economy in cortisone dosage may be obtained by giving the two substances together. Unpublished observations by Seneca and Ellenbogen on the action of steroid hormones on adrenocortical enzyme systems *in vitro* provided the rationale for these studies, cortisone may effect the synthesis of a tissue carbohydrate, and insulin may enhance this activity and make activation products of glucose readily available for tissues without requiring conversion from amino acids.

Observations were made on nine women and three men, with rheumatoid arthritis in various stages (I-IV)² and of various durations (6 weeks to 20 years). Glucose tolerance tests were performed in all cases, and though the fasting blood-sugar was within normal limits there were cases in which return to the normal level was delayed. 12.5-50 mg. of cortisone acetate in an aqueous suspension and 20-60 units of plain insulin were then injected daily in single or divided doses during successive 10 day periods. No clinical improvement was noted during 10 days in four patients given 12.5 mg. cortisone and 20 units of insulin, but in six of eight patients given 25 mg. of cortisone and 40 units of insulin for 10 days a rapid fall in sedimentation rate occurred, and four had definite signs of clinical reversal. All twelve patients were then given 50 mg. of cortisone and 40 units of insulin for 10 days, and during this period ten progressed to normal sedimentation rates and eight to well marked clinical reversals, grades I and II. The patients also gained 4-29 lb. in weight. This dose of 50 mg. of cortisone is only half the amount (100 mg.) usually given daily, and further clinical benefit seemed to be obtainable at a dosage of 25 mg. of cortisone and 40 units of insulin. Except possibly in one patient who developed oedema of the ankles, no side effects attributable to cortisone were observed during the 30 day trial period. Hypoglycaemia was readily controlled and was not related to the degree of response.

Though Messrs Merck and Co. have recently reduced the price of cortisone from \$95 to \$50 per gramme,³ treatment is still expensive. Henderson and his colleagues hope that critical evaluation of their work may establish a safer and more economical use of cortisone, and some explanation of its pharmacological action.

EFFECTS OF CLIMATE ON ANIMALS

If cattle could be made to produce beef and milk in warm climates at something like the level attained in temperate climates, a great advance would be gained against undernourishment. To this end many tropical countries have tried to improve their stock by importing productive animals from temperate zones, either for pure or cross breeding, but only brief increases in production are achieved before the imported stock and their cross bred progeny show deterioration. Kelly suggested that the most useful thing to do would be to isolate studs of milking strains of tropical zebu cattle under European control in a country where the herds could be expanded free from disease and made available to countries that needed them, but J. D. Findlay and his colleagues at the Hannah Dairy Research Institute while commending this proposal, think that the fundamental

question of temperature regulation in cattle should be studied. As a first step to such a study Findlay has reviewed existing knowledge.

In hot climates, he says, tropical cattle can stand more than those imported from temperate climates and field tests show that their body temperatures are influenced by high air temperatures and humidity, respiration rates are also less liable to increase, and criterion woolly coated animals are less able to stand than those with glossy coats. Contrary to what is man, the pulse rate of cattle is increased by heat and prelude to complete breakdown under extreme conditions. The skins of tropical cattle often allow considerable loss by diffusion, but it is still uncertain whether capable of active sweating. These and many other animal physiology require further investigation by the methods commonly used in human physiology. Our information about climatic effects on farm animals has been gained by simple methods, and though some of these are admirable for their purpose others are crude and for their own investigations the Hannah Institute built a psychrometric room, suitable for the study of at a time, in which the temperature, humidity, and wind may be varied independently and kept almost at any given level. This room and its adjacent chamber are equipped with the modern apparatus for accurate and continuous recordings of the animal and the cow's reactions.

One chapter of Findlay's monograph briefly surveys effects of tropical environments on sheep, pigs, and fowls. The pig is particularly sensitive to changes, and it plays a larger part in the agricultural economy of Great Britain than of the Colonies. For this reason perhaps, some recent studies⁴ of its reactions to the hot climate were concerned with the effects not of excessive heat but of excessive cold.

THE CHSC

At the Trades Union Congress on Sept. 5 Dr. H. B. Cant, secretary of the Medical Practitioners' Union, said he was like to see the constitution of the Central Health Services Council revised so that it became a great body representing all the people in the National Health Service, including nurses and even cleaners. It should then be wider functions as the permanent advisory planning mission. At present, he declared, there was no plan for future development of the service as a whole.

DIAGNOSIS OF GASTRIC CARCINOMA

THE diagnosis of gastric carcinoma is often baffling to the surgeon intervenes or the march of the disease doubtful. Papanicolaou's method of establishing the presence of malignancy by examination of exfoliated cells¹ has already proved of value in gastric cases², and now, with his colleagues,³ he has developed a refinement which seems promise still greater accuracy. Broadly, this consists in producing mechanical irritation of the gastric mucosa by means of an inflatable balloon rendered abrasive by untreated braided silk on its surface. Of 33 cases where diagnosis was later established by operation or biopsy, 17 cases of proved malignant disease, smears by washing the balloon after withdrawal yielded malignant cells in 12 (two Hodgkin's disease). The benign lesions produced no positives.

This procedure appears somewhat heroic but it has already led to any hemorrhagic or other serious complications. There is largely no doubt because it has not been used in the presence of supposed active upper gastro intestinal bleeding, gastric perforations, oesophageal varices, or complete obstruction. The results recorded are impressively better than those the same workers obtained on the same patients with routine smears from gastric aspirate.

WESTERN UNION

Public health committee of the Western Union Powers successful sixth session from Sept 7 to 9 in Edinburgh study of health services in relation to civil defence and, by the exchange of documents visits of experts, establishment of a subcommittee which will meet on Nov 21. A uniform system of health control of ships, similar to that already in force for air traffic will be introduced by March 1, 1951. In practice this will mean that ships will have freedom from control of ships arriving here between Brest and the Elbe will be extended to the Mediterranean coasts of metropolitan France and session will be held in Marseilles on March 20.

APPLICATIONS OF CARDIAC CATHETERISATION

Recent reports from the U.S.A. indicate that catheterisation of the heart, though usually accomplished without trouble, is a very unpleasant and even dangerous effects. Southworth reports the case of a 25 year-old woman with congenital disease in whom a catheter was advanced from the femoral vein (the arm veins being unsatisfactory) into the right ventricle. Ventricular fibrillation started and lasted for at least three quarters of an hour during which oxygenation was maintained by cardiac compression and artificial respiration. Normal rhythm was restored after administration of procaine hydrochloride and procaine hydrochloride with small amounts of adrenaline, and electric shock. Bruce et al. record a case of cardiac enlargement (Wolff Parkinson White syndrome (abnormally short P-R interval, usually prolonged QRS complex, and history of paroxysmal tachycardia) in which the introduction of a catheter from the right arm to the region of the tricuspid valve led to multifocal ventricular tachycardia. Nine hours after other measures had failed, atropine sulphate (0.0012 g) promptly converted the ventricular tachycardia to a supraventricular tachycardia resembling atrial flutter, which changed to sinus rhythm with a normal rate. Lastly Michel et al. report that of 133 patients treated under fluoroscopic control to cardiac catheterisation, usually under local anaesthesia, via the antecubital vein, 37% developed an arrhythmia. The incidence of arrhythmia was 19% with the catheter tip in the right atrium, 19% in the right ventricle, and 19% in the pulmonary artery and the incidence was higher in patients with congenital heart-disease and in those with pre-existing electrocardiographic abnormalities. The arrhythmia was usually except in one case, in which the patient died of the catheter induced arrhythmia, together with respiratory depression of the respiratory centre may it have contributed to the fatal outcome.

PUBLICITY FOR CANCER

In the *Medical Officer* for Sept 9 Dr Malcolm Donaldson raises again the question of more active instruction of the public on cancer and the advantages of early treatment. He points out that great numbers of people have erroneous ideas about the disease and are too much afraid of it, and he thinks that this fear is increased by being bottled up. 'In America and some other countries he says, all taboos concerning cancer have been removed and people talk about it freely' but in this country 'scarcely any newspaper will mention the word 'cancer' unless some institution is prepared to pay heavily for an advertisement'. From this standpoint it is perhaps all to the good that the *Nature* journal, with an immense circulation, should have the courage to publish last week a long illustrated article on cancer. It is likely to weaken the taboo. But we would wish that the article were not devoted to the claims of a unorthodox method of treatment whose nature remains undisclosed and whose value is, to say the least unproven. Since 1919 Mr David Rees Evans has been using, with modifications, the 'Cardigan cancer cure' which was brought before the public more than forty years ago, and since last November he has treated 16 cases at the Presbyterian Hospital, Newark, New Jersey. Anyone unfamiliar with the history of other cancer cures is likely to feel that the initial results

in these cases, and the supporting data, make an authoritative investigation urgently necessary, but the medical profession has a well founded objection to the treatment of patients with unknown remedies, and these objections are not entirely met by Mr Rees Evans's willingness to 'disclose the full details of his preparations and methods of treatment to a properly constituted committee, following tests under agreed conditions of control' (our italics). The first requirement seems to be a considered report from the American doctors who gave him facilities.

Dr H. MORLEY FLETCHER consulting physician to St Bartholomew's Hospital, died at his home at Petworth on Sept 9, at the age of 85.

Reviews of Books

Recent Advances in Pharmacology (London J & A Churchill 1950 Pp 418 24s) —To display the growing edge of a new science is by no means easy. Recent advances must in fact be recent enough to call for comment, yet a reasonable period must elapse before fresh claims can be related to the background of established knowledge. The publishers of this book may be congratulated on their choice of authors, for Prof J. M. Robson of Guy's Hospital Medical School, and Dr C. A. Keele, of Middlesex Hospital Medical School have produced a notable addition to pharmacological literature. They conduct the reader through the labyrinth of new knowledge of such substances as the anti cholinesterase drugs, the anti histamines and the steroids of the gonads and adrenal cortex—to mention but 3 of the 18 chapters. The section on the mode of action of drugs is masterly, and that on the evaluation of the actions of drugs in man deserves the subtitle "statistics without tears". References are abundant and errors very scarce. The book is likely to be in great demand among students of pharmacology and postgraduates in general medicine.

Organic Chemistry (4th English ed London Cleaver Hume Press 1950 Pp 983 57s 6d) —Prof Paul Karrer, of Zürich, is a mine of information about organic reactions and structure, but it is unfortunate that he records incorrectly, or discusses from outmoded angles, many points of particular interest to doctors. Thus in the description of alcoholic fermentation the energetic aspects, including the rôle and production of ATP, are neglected, and Scottish readers will be horrified to read that whisky is made from maize or rye, neither of which is used in the production of 'Scotch'. There are some other biological mis-statements and omissions: no mention is made, for instance of recent advances in the analysis of protein, carbohydrate, and carotenoid by the application of chromatography. It is to be hoped that in the next edition the more biological sections will be efficiently revised so as not to detract as they do at present from the value of the purely chemical information.

Modern School Hygiene (14th ed London James Nisbet 1950 Pp 480 12s 6d) —This book by Dr R. Gamlin, chief assistant school medical officer for Liverpool, is essentially a reference work on matters relating to the school medical service, and it is intended for teachers rather than doctors. It opens with a chapter on heredity, and chapters follow on elementary physiology and pathology and their applications in child health. These are lucid and to the point, but perhaps rather dogmatic. For example the assertion that only full cream dried milks should be used in infant feeding would not find general acceptance among clinicians. There are some good chapters on physically handicapped pupils, mental defectives and educationally subnormal children explaining the educational facilities for them under the Education Act. The common infectious illnesses are described but a serious omission is the streptococcal throat, which next to the common cold, is the commonest infection among school children. The passages on poliomyelitis make no mention of abortive infections. The book concludes with an interesting chapter on school architecture, a short glossary of medical terms, and a bibliography. The author seems happier when dealing with the administrative than with the clinical aspects of school hygiene, but on the whole he does what he sets out to do for the school teacher, and he provides some useful sections for the doctor concerned with education.

British Red Cross Society First Aid Manual, No 1 (9th ed London Macmillan Pp 300 3s) —The first new edition of this famous manual for ten years has been largely rewritten and since the authors are Sir Harold Whittingham and Sir Stanford Cade, this has been done very adequately indeed. Material has been added to cover the needs of Civil Defence in air raids, including atomic warfare, and there has been a welcome pruning of theory and concentration on the really practical aspects of the subject.

Introduction to Physical Biochemistry (2nd ed London Cassell 1949 Pp 246 27s 6d) —This book, first published in 1941, has been considerably revised without structural alterations. The opening chapters are concerned with those physical properties of water, solutions, gases, and colloids which play an essential part in body processes, while later chapters discuss chemical equilibrium, buffer systems, respiratory functions of blood, oxidation reduction systems, and the acid base balance of the blood. The author, Prof J M John, of Vanderbilt University, might be more explicit in his references to 'larger textbooks,' but his book certainly forms a readable introduction to an aspect of biochemistry which can easily be made dull and unintelligible.

From Letters to the Editor

Intrathecal Tuberculin —Though I do not wish to dispute the observations and conclusions of Dr Smith and Dr Vollum (Aug 19), I think that an alternative and simple explanation of the dramatic recovery of these patients is possible and should be excluded before any large scale trial of intrathecal tuberculin is undertaken. Choremis and Vrachnos (*Lancet*, 1948, ii, 408, 513) have emphasised the intense meningeal irritation which can be caused by intrathecal streptomycin, which may superimpose a chemical meningitis on an infective one. Increasing opisthotonos, repeated uncontrollable vomiting, and hydrocephalus due to subarachnoid block are results observed by Choremis following intrathecal injection of 100 mg or more of streptomycin. It is perhaps significant that in Dr Smith's cases tubercle bacilli were no longer to be found in the c s f when intrathecal tuberculin was started, and even more so that it was only some days after all intensive intrathecal therapy had been discontinued that improvement took place. Furthermore there was no opportunity of observing the possible deleterious effects of another course of intrathecal streptomycin during the surprisingly smooth convalescence of these two 'hopeless' cases. Is it not possible that what actually happened was that the initial course of chemotherapy had to all intents and purposes replaced the tuberculous meningitis by a chemical one, and that this was being perpetuated, whether by streptomycin intrathecally or by the even more noxious tuberculin (T.P.D.)? When all intrathecal interference was discontinued, the meningeal irritation ceased and the patient recovered. —S L O JACKSON, M.R.C.P. (Brompton Hospital London SW 3)

Teaching at Non-teaching Hospitals —Whatever may have been the teacher's training, his success in imparting knowledge and understanding depends on his desire to teach, and his possession of an animating and dynamic force. The University Grants Committee warns against promotion based solely on research, rather than on personal qualities and teaching ability, yet how few excellent clinical teachers are so encouraged. I would plead for a return to teaching of the simple clinical methods, the inculcation into the student of the elemental necessity of training his senses, the assembling of the facts in a reasoned manner and direction in the way of interpreting them along physiological and pathological lines. When these have been mastered then is the time to fortify and confirm the clinical diagnosis by the ancillary investigations which it seems the student must know.

Clinical material in the teaching hospital is limited, but many men who have had experience in teaching hospitals occupy positions on the staffs of non-teaching hospitals and efforts should be made to include them in the teaching of medicine. Not only students but also registrars could benefit from the teaching of some of those clinicians who may have hitherto thought themselves 'out in the wilderness' and it is to be hoped that regional boards will have the vision to encourage a proportion of their registrars to go to non-teaching hospitals. —W R BLACK F.R.C.S. (Weston)

In England Now

What a week! Telephone ringing day and night.

brr Brr brr Brr brr

From an Old Faithful — 'About this B.B.C. appeal, I'm a regular donor and should like to give my blood. I'm a rare group.' — 'What is your group?' — 'Group minus.' — 'Thank you very much for ringing us, but, it's the exact group we want.'

From a Facetious Houseman — 'Hallo! I've got the what?' — 'What man?' — 'His group is ODECE.' — 'Is it big D or a little D?' — 'I don't know what you mean.' — 'Caesar D for Daddy E for Erythroblastosis (Ha! Ha!) it's said I is it a capital D or a small D?' — 'I don't know and I'll find out. A minute or two later.' — 'Sorry little D and' (he bursts into song) 'the other is a little D (Ha! Ha!)'.

From a Very Superior Person — 'I've just been on the radio and I shouldn't really mind giving a plot of my that poosh woman.' — 'Yes, madam and what is your group?' — 'I really don't know but I am a real type.'

And so it went on, day after day, night after night, calls from the hopefuls, the enthusiasts, and the types—alphabetical explanations, permutations and combinations, the C's, the D's and the E's, the little C's little D's and the little E's. How the gods and Wiener must have laughed!

Preclinical Teaching —Dr Johnson (Aug 26) in the Moran Committee as saying that the average graduate tends to lack curiosity and initiative and his power of observation are relatively undeveloped. She then describes exercises aimed at forestalling these deficiencies, calling for an effort by the student. But if it is important to train the student to observe it is even more important not to destroy his natural desire to learn. Often he is frustrated by methods of instruction which, though necessary, are remote from practical reality and encourage a cunning to learn the 'tricks' of examiners rather than to seek knowledge for its use in his future medical work. Clover even should not enable the lecturer and demonstrator to come out of their laboratories to instruct, for personal example is the best means of inspiring and encouraging good habits. If the teachers themselves really show insight, method, enthusiasm, and powers of observation the student will follow their example. The closer the teacher-student relation, the higher the quality of the learning and the greater opportunity for initiative. —MEDICAL STUDENT

Preclinical Education —Dr Johnson refers to the unscientific approach of students to scientific problems, and Dr Dicks deplores the lack of the human aspect in preclinical training. It looks as though the student is to have two further calls on his time—discussion periods and anthropology. But the fault, and the opportunity for its remedy, are to be found at an earlier stage for the neglect of the human and of a scientific attitude to scientific matters starts at school. This is not the fault of the teachers, it is the hospital and university entrance examinations which are the root of the trouble. As long as it is possible to pass these with little more than a stock of factual knowledge, the schools will, and must, provide this first and foremost. As soon as a more general education becomes essential for passing these entrance examinations, much of the ground for Dr Johnson's and Dr Dicks's just criticisms will be removed. —JOHN L. STRUTHERS

Antimalarial Drugs —As you say (Aug 19), quinine amblyopia is rare in West Africa. However, your remark that 'it would be wrong to assume that blackwater fever has disappeared from West Africa since the almost universal application of mepacrine calls for comment. It is true that blackwater fever has not entirely disappeared but it has become strikingly uncommon despite the increase of the non-immune population in all four West African dependencies. In Nigeria during 1931-1942 the average number of cases was 15 per year in the non-African population averaging 6000, during 1943-49 the average number of cases was 1 per year in a population averaging over 5000 and during 1948-49 there were only 3 cases of blackwater fever in a population of about 11 000. Moreover, of these 3 cases, 1 was in a patient known to take quinine as a suppressive. The decrease of the incidence of the disease in non-Africans from 1943 onwards coincided with the general substitution, first of mepacrine (1943) and then of proguanil (1947) for regular suppressive quinine. Treatment of acute malaria with quinine alone or combined with other antimalarial drugs is still favoured by many medical officers.

and there is no evidence that the *therapeutic* use had any bearing on the incidence of blackwater fever and similarity of the above findings to those of 1941-45 for European military personnel in West Africa, and confirms the close relationships of this suppressive quinine medication—LEONARD J. WATT, M.D., senior malarologist, Nigeria

Apkinless Age—I was interested to read (Aug 12) of the new plastic napkin containers for use with disposable napkins. Similar containers have been used in Switzerland, and I have been using them for the last eight months (since she was 6 months) have found them most satisfactory though I have using the disposable cellulose fillers for three reasons: (1) they are expensive, (2) they tend to disintegrate when stuck to the baby's skin, thus obliging one to wash at every nappie change and (3) they are not fully absorbent. Instead, I find that an ordinary gauze napkin, folded to the appropriate shape and when soiled, is easily washed. Since the use of these containers is rather erratic I have begun them myself, and find them very cheap and easy to use—MURIEL WOOLMAN (Basle Switzerland)

Treatment of Urinary Bilharziasis—I have tried 'Nilodin' (B.W. & Co.) a preparation of Miracidol sugar-enteric-coated pills in three proved cases of *schistosoma haematobium* infestation. The dose régime was recommended by the manufacturers—i.e., a total of 10 mg per kg body weight given as 10 mg twice daily for 10 days. One of the patients received two courses with a 2-week interval between them; he discharged himself still passing ova in his urine. The second patient had only one course and discharged himself with ova in the urine. The third, who is still in hospital, continued to pass ova after 2 courses, but was cleared after a course of 'Fantom' (phen) which is sodium antimony bispropionate 3.5 mg in disulphonate. This patient is now under treatment for secondary anaemia only. This confirms the observations of Alves (*Lancet*, 1950, 1, 1) and I must add that the sugar enteric-coated nilodin is poorly absorbed in the Iraqi gut too—DR M. FAWZI, Department of Therapeutics, Royal College of Medicine, Baghdad.

Protection of the Skin from Sunburn—Dr Russell Dr Anderson says in their article of Aug 12 that there is no evidence that the anti-histamines by mouth are of use in sunburn. Yet they seem to have missed the opportunity of testing this to the test in their case. Earlier this year I had a case similar to theirs. The patient, also a civil servant, 53 years of age and had become hypersensitive to sunlight after 20 years. I prescribed both 'Anthusan' (10 mg t.i.d. by mouth) and as a light screening agent *p*-aminobenzoic acid in paraffin (I asked for this substance in the hope that it would be obtained quicker than the reputedly effective ethyl *p*-diethylaminobenzoate). However, there was a delay of 5 days in getting the substance and during this time the anthusan cured the patient who was able to resume work—S. SHUBSACH, M.R.C.S. (Manchester)

Enuresis and Hypersomnia—Dr Ström Olsen's case reports in his article of July 22, may lead to the idea that wetting in heavy sleepers who have no obvious signs of enuresis is secondary to the deep sleep. The enuresis and hypersomnia may be unconnected.

A girl, aged 6 years, had always wet the bed. She was a deep sleeper and was not conscious when raised at night to late. The family seemed a united one, and her mother noted no symptoms of anxiety. In the 17th psychiatric interview she drew a scene from *Hansel and Gretel* which was interpreted to her in terms of her own aggressive feelings to her mother. She was indignant but only had two wet nights in the next three weeks, and then only one wet night in six weeks. Her mother stated however that she slept as heavily as ever.

A boy, aged 12 years, athletic, intelligent, jolly and with many friends had wet the bed since birth. His family seemed united and made no other complaints about him. He was a deep sleeper and was raised by his parents twice nightly. He had received medical treatment for three years without benefit and psychotherapy had no obvious effect on his

behaviour or enuresis. It showed, however, that he had no overt anxiety, that he was reluctant to take responsibility, and that his expressed fantasies contained remarkably few female figures or symbols. In the course of treatment he developed erythema nodosum and was hospitalised. The ward sister, forewarned, kept him dry for five weeks by raising him at increasing intervals during the night. He was then sent home with an alarm clock, and his parents were told to delegate full responsibility for dry beds to him. He remained dry for two weeks and then relapsed. It was found that his parents had again resorted to lifting him as 'he is too deep a sleeper to set the alarm for 5 A.M. after it has woken him at 11 P.M.' They were discouraged from their over-indulgent attitude, and he was dry again for a further month, setting the alarm himself and waking to urinate. He relapsed again, completely, following a threat to send him to boarding school if he refused to abstain from athletics following his attack of erythema nodosum. This new bout of wetting was accompanied by open defiance of his parents and small destructive acts.

The first case shows that cessation of bedwetting in a deep sleeper is not necessarily accompanied by lighter sleep. The second case shows how over-dependent enuretics with over-protective parents may use the excuse of deep sleep to serve their own ends—RICHARD MEYER, M.R.C.P. (Hospital for Sick Children, Great Ormond Street, London, WC1)

Patients' Travelling Expenses—The changes in conditions under which travelling expenses may be paid (*Lancet*, Aug 12 p 273) will throw an added burden on the staffs of the National Assistance Board and chest clinics and the financial saving will be paltry in the case of tuberculous patients. For many years free travel to and from sanatorium has been included in the tuberculosis service without regard to the income of the patient. The reintroduction of a means test in this connection is highly retrograde and we even foresee the possibility of a patient's admission to sanatorium being hindered by the time taken by, and/or the result of, the National Assistance Board's inquiries. It would have been better if the Ministry had not made these changes without due regard to the special circumstances of the tuberculous who often have to travel long distances for sanatorium treatment and who by the time a vacancy is offered have usually suffered considerable financial reverses. The Minister recently voiced his concern at the grave problems involved in the treatment of tuberculosis, and we hope he will reconsider this additional difficulty he has imposed—C. W. L. JEANES, M.R.C.S. chest physician, Greenwich, B. J. MALLEY, M.D. chest physician, Bermondsey, C. F. PRICE, M.B. chest clinic, Camberwell, E. K. PRITCHARD, M.R.C.S. chest physician, Southwark, J. P. V. RIGBY, B.M., chest physician, Deptford, J. E. STOKES, M.D., chest physician, Lewisham

Endometrial Tuberculosis—Within the past four months it has been stated (*Lancet* 1950, 1, 733 and Aug 5, p 220) that Mr J. A. Stallworthy has achieved apparent cure in 5 of 6 patients treated with streptomycin and that apparent cure is presumed after three consecutive negative tests at monthly intervals. The first is encouraging news, but I feel that as pelvic tuberculosis is a blood-borne disease and the focal point must often be outside the field of gynaecology, the absence of lesions in biopsies for the short time of three months after treatment is not sufficient evidence of cure. In our smaller series biopsies and cultures have more than once been negative for more than a month in untreated cases—MAGNUS HAINES, M.D. (Chelsea Hospital for Women, SW 3)

Psychiatric Social Worker—I agree wholeheartedly with the opinions expressed in your annotation and by Dr Sessions Hodge (Aug 12). The skilled psychiatric social worker plays an essential part in the field of psychiatry and her place cannot possibly be taken by those whose experience has been confined to administrative work. In the week when the Nottingham County Council's advertisement appeared in the B.M.A. annual conference devoted a session to the role of the psychiatric social worker at which members deplored the shortage of trained workers and made suggestions for the most profitable use of the small number available. It was felt that the profession could not hope for the necessary expansion unless a reward was offered to some extent commensurate with the requirements of long training, high

personal qualifications, and arduous and exacting work. The existing negotiating machinery seems to be doing nothing to remedy the present anomaly in the salary scales. To perpetuate these conditions seems to be a strange policy for a Ministry whose professed aim is to base a complete National Health Service upon highly qualified and skilled personnel — DESMOND CURRAN, F.R.C.P. (St George's Hospital, London, S.W.1)

Origins and Outcomes of the Patient's Stay in Hospital—The final section of the article by Miss Addiscott and her colleagues (Aug. 26) suggests that the almoner may make the patient aware of her critical attitude towards his habits in such a way as to cause resentment. But in fact one of the main objects of her training is to enable her to establish a good relationship with her patient as the basis of her social therapy. The question of criticism, overt or implied, seldom arises, but where it does, the good contact established should enable the patient to absorb and act upon the almoner's suggestions for his welfare without the resentment which would be as disastrous to the almoner-patient relationship as to that between doctor and patient — MARY W. WINDSOR, A.M.A., ELIZABETH ALEXANDRE, A.M.A. (Manchester Royal Infirmary)

Ways into General Practice—Your leading article of Aug. 26 says that the easiest path to the status of principal is by preliminary assistantship. The *British Medical Journal* of Sept. 2 contains two advertisements of vacancies for assistantship with view and twelve advertisements from practitioners requiring an assistantship with view. Inquiry at the Medical Practices Advisory Bureau would also show that there are many more applicants than openings. You say that "the chances of getting into practice seem rather less bleak than they have sometimes been painted." This may be so, but it is unsatisfactory that they should be bleak at all, in view of statements on behalf of the Government that the entry into general practice would be facilitated by the Health Service. In fact it has been made more difficult, and

a real effort should now be made to fulfil the promise of the Doctor.

Inoculation Certificates Required Abroad—British Overseas Airways Corporation has the most information in this country on the requirements of governments regarding certification of vaccination inoculation needed by travellers by air. This is obtained from the World Health Organisation's *Epidemiological Record* and daily broadcasts, the M.H.S.'s weekly return of infectious diseases and the reports from the Corporation's agents throughout the world. I support your footnote to the letter from Sir Philip Bahr (July 22), to the effect that doctors requiring information on this matter should apply to the M.H.S. Department, British Overseas Airways Corporation, House, Piccadilly, W.1 (Tel. Mayfair 6811) or to its representatives in the U.K. of the countries to which the traveller intends to visit or transit — Sir HAROLD W. BAM, F.R.C.P., director of medical services, B.O.A.C.

An Unconscionable Time A-dying—The entitled article by Dr. Jackson in your issue of Aug. 26 is an experience this year in a staggeringly expensive home.

I was awakened by a choking sensation and an overbearing stench. Knowing that large industrial concerns were near I thought "an explosion" and struggled from beneath the window, from which I imagined the fumes were entering. Worse ensued however. Knowing that the ringing produced negative results, I emerged again to the lean out of the window. That was better, and after a time it struck me that some over-fumigation process was going on nearby. True enough, a patient had died and the bed was urgently wanted, so combined sulphur and formaldehyde had been decided upon to hasten the process. One day the staff seemed pained to think that their zeal had been appreciated, quoting quite recent textbooks on the subject of disinfection — ESTHER CARLING, M.D. (Northwood, Middlesex)

Notes and News

Goeffaerts Gastrectomy Clamp

Mr Geoffrey Parker, F.R.C.S., writes: Many British surgeons in the later stages of the war enjoyed the hospitality of Dr Goeffaerts, of Alost, in Belgium, and admired his effortless technique. His untimely death, on the eve of his appointment to a surgical chair, deprived Belgium of one of her finest operators and teachers.

The clamp that I use in subtotal gastrectomies (made by John Bell & Croyden Ltd., London, W.1) was designed by Dr Goeffaerts. It is essentially a large size Payr clamp with a longitudinal groove through each blade (see figure). It is applied in the usual way at the site determined for cutting across the cardiac end of the stomach. The distal portion of

the stomach is closed with a straight Doyen's clamp to prevent soiling and cut away. Interrupted linen thread sutures are then passed through the slits in the blades and tied off, and the ends are cut short. The clamp can be removed before or after inserting the outer layer of sutures of the anastomosis to the duodenum or jejunum. After its removal, the part of the stomach to be used for the anastomosis is kept closed with straight Kocher forceps while the part not so required is closed with a second layer of continuous or interrupted sutures. The anterior layers of the anastomosis are inserted as usual, a Hofmeister valve, if required, is made by fixing the proximal jejunum with interrupted sutures along the line of the closed portion of the stomach. In over 100 consecutive gastrectomies where this clamp has been used I have had no postoperative bleeding from the anastomoses, in spite of the attempts of enthusiastic house surgeons to relieve non-existent hæmorrhage and distension with gastric suction. All the patients took unrestricted fluids by mouth 12 hours after operation the only proviso being that they must drink from a teaspoon to avoid too rapid filling of the gastric stump.

Notifications of poliomyelitis in the week ended Sept. 9: paralytic 302 (previous week 369), non paralytic 189 (220), 401 (589). The only counties showing more than average increase were Kent and the West Riding.

At the University of Edinburgh on Oct. 9, 10 and 11 Mr. N. Tanner will give three lectures on the Surgical Treatment of Ulcer. On Oct. 13 Dr. Philip S. Hench, of the Mayo Clinic, will speak on the Present Status of Cortisone and ACTH in Internal Medicine. All these MacArthur lectures will be given in the anatomy lecture theatre, University New Buildings, at 5 P.M.

The following have been admitted to the fellowship of the Royal Faculty of Physicians and Surgeons of Glasgow qua Physici et Chir: Colin R. J. Outhbert, J. C. C. Kelly, R. J. McWilliam, S. M. J. R. J. McMurdoch, G. B. Shaw.

On Friday Sept. 22 at 11 A.M. at the University of Liverpool the Biochemical Society is holding a symposium on the chemistry of Fish.

Dr. Leonard Colebrook, F.R.S., and Dr. J. P. Bull will speak at the symposium on burns which the National Research Council is holding in Washington at the request of the Department of Defense on Nov. 2, 3 and 4. Those wishing to attend should notify the secretary of the division of medical sciences of the council, 2101 Constitution Avenue, Washington 25, D.C. U.S.A.

The Medical Research Council invite applications from not qualified men or women with one or two years' experience in appointments for a studentship (£500 p.a.) for training in research of experimental psychology, tenable at the psychological laboratory of the University of Cambridge for not less than one year. Applications to be returned before Oct. 1 may be had from the secretary of the council, 38 Old Queen Street, London S.W.1.

The chief medical officer of the Ministry of Health has asked all general practitioners a list of proprietary medicine which they have advertised direct to the public. Following the report of the committee on prescribing (*Lancet* July 8 p. 66) he has asked them to try to avoid prescribing any of the substances on the list. In your professional judgment you feel clear that there is a special justification for doing so in any individual case?

The Charity Commissioners propose to establish a scheme for the regulation of the Benevolent Medical Society of Hertfordshire. The scheme can be seen at 2 Parliament Street, and copies can be bought at the office of the commissioners (25, 2d). Objections or suggestions may within 21 days be made to the secretary of the commission, Ryder Street, London E.C.4.

The classification of junior hospital posts as A, B, or C is to be discontinued from Sept. 30.

The National Institute for the Deaf has published a new application list of manufacturers and suppliers of deaf aids who have entered into an agreement with the institute as to their methods of fitting. The list (price 3d) may be had from the institute, 10, 11, Street, London W.C.1.

e investigation shows that it takes on an average 10 minutes to fit and supply a pair of spectacles under the Health Service (Report of Working Party Part 1, Ministry Office, Pp 36-38). To dispense a pair for a patient took 45-47 minutes. The ratio of repairs to new about 11%, but as most of the N.H.S. glasses are at it is thought that this will probably increase to about 15% and take an average of 9-14 minutes.

The Epilepsy Association founded in July as a memorial to the late Mr. Fox met on Sept 5 with Lady Cynthia Colville in its aims include the general education of the public and the special education of those in charge of epileptics, the creation of an information and advisory service, the establishment of hostels and convalescent homes. The national council are Sir Charles Symonds, Dr Russell, Dr MacDonald Critchley, Dr Letitia Fairfield and Dr Williams.

The fourth reunion of the 2nd British General Hospital in the 1940-45 war will be held on Saturday Oct 7 at Simpson's Restaurant, Strand, London W.C.2. Tickets may be had from Dr J. H. Eaton, 25, Biddenham Turn, Bedford.

The responsibilities of the veterinary profession should not stop at the farm gate, declared Mr. John Bruford in his presidential address to the National Veterinary Association at Cardiff on Sept. 6. To ensure cleaner food, he held that the veterinary surgeon should have authority to inspect it up to the time it is bought by the housewife.

During 1949 the number of voluntarily registered disabled persons rose by 27,000 to over 935,000, of whom 131,513 were pensioners of the 1914-18 war and 415,021 were other ex-service men and women. (Annual Report of the Ministry of Labour and National Service for 1949, H.M. Stationery Office, 4s.)

During the war years Revers (1946) noticed that patients suffering from peptic ulcer improved taking a proprietary preparation purchased from a pharmacist in a small Netherlands town. This preparation was found to consist of a mixture of succus liquorice, fructus anisi, and ferrum reductum. Supposedly the therapeutic effect was due to the liquorice, but a series of gastric ulcer patients with a paste consisting of 2 parts powdered succus liquorice and 1 part water. The patients had to take one teaspoonful 4 times a day, on an empty stomach. No restrictions in diet or activity were imposed. The majority of the patients became symptom free within a short time, and examination revealed that sometimes a deep ulcer on the lesser curvature disappeared within three weeks.

In 1945 succus was no longer available. In 1947 the same favourable results could be obtained, but this time no side-effects were observed, which had not been the case before. Approximately 1 in 5 patients treated with the paste developed oedema, usually noticed first in the legs and later in other parts of the body. Many patients complained of headache, and some noticed shortness of breath on exertion and pain in the upper abdomen (Revers 1948).

On reducing the dosage the symptoms usually subsided, but in some patients they remained so severe that the treatment had to be discontinued. Patients who had responded with oedema developed it again when the drug was given a second time. But Dr Revers did not regard the reaction as allergic, for there was no change in the eosinophil-count and anti-histamine drugs were ineffective. He recalled having previously seen a case in which oedema disappeared when the patient stopped eating sweets containing liquorice and returned as soon as she began to eat them again. Another case of the same kind was reported by Dr G van den Bergh at a meeting in Amsterdam on Feb 25, 1950. Dr H Pannekoek mentioned a patient who had never had symptoms of cardiac failure but developed severe cardiac asthma after taking liquorice for his stomach complaints, and several similar cases have since been noted by Belgian and Dutch doctors.

PRESENT INVESTIGATION

Succus liquorice is a dried watery extract of the roots of *Glycyrrhiza glabra*. It contains 15% protein substance, 5% glycyrrhizin, 40% "extractable" substances, 5% sugar, and 5% insoluble substance. It is generally used by pharmacists to make pills and to mask unpleasant tastes. (The quantities used for this purpose are, we have found, not much less than those known to provoke cardiac asthma in susceptible elderly people.)

After Revers reported his findings investigations in the pharmacological institute of the University of Utrecht demonstrated that the drug had a powerful

spasmolytic action and also prevented experimental production of gastric ulcers in rats and guinea-pigs. Glycyrrhizin was shown not to be the active principle. Administration of succus liquorice to several species of animals failed to produce oedema, nor could any influence on water and sodium chloride metabolism be demonstrated (Nelemans Stamperus 1949).

Obviously the problem of the oedema had to be studied clinically. The possible causes of generalised oedema are

- 1 Reduction of serum albumin to less than 60% of normal
- 2 Increased permeability of the capillary walls, reducing the effect of the colloid osmotic pressure of the serum-proteins
- 3 Disturbance of cardiac function leading to heart-failure
- 4 Primary retention of water and sodium chloride by the kidney, due to (a) damage to the kidney leading to a severe impairment of renal function, or (b) hyperfunction of the tubules reabsorbing water and sodium chloride excessively

As possibilities 1 and 4a were soon ruled out, we had to decide which of the three other mechanisms was responsible for the fluid retention. They can be distinguished by the scheme shown in the following table, and in order to apply it we had to collect data on the changes in haemoglobin, total proteins, venous pressure, blood pressure, and pulse pressure.

SCHEME FOR ASCERTAINING CAUSE OF OEDEMA

	Hæmoglobin and total proteins	Venous pressure	Blood pressure (systolic)	Pulse pressure
Increased capillary permeability	Increased	Decreased	Decreased	Decreased
Primary heart failure	Decreased sometimes secondarily increased	Increased	Decreased or unchanged	Decreased or unchanged
Primary renal retention of water and sodium chloride	Decreased	Increased	Increased	Increased

During the past eighteen months we have given succus liquorice to seven patients in our department who, in spite of long continued dieting and bed rest, had persistent symptoms and X-ray evidence of gastric ulcer, and to three other patients. So as to get reliable data on the electrolyte balance and on the time relations between the use of the drug and retention of water and sodium chloride, we gave eight of the ten patients a strictly standardised diet, consisting of exactly the same amounts of milk, biscuits, and butter, at three hourly intervals by day and by night, just meeting their calorie requirements. Before receiving food at exactly midnight, 3 A.M., 6 A.M., &c., the patients passed urine. All 8 specimens were measured and examined for chloride and for urea plus ammonia. All the patients showed the excretory rhythm described elsewhere (Borst and de Vries 1950).

With each feed, the patients received supplements of constant amounts of sodium chloride and sodium bicarbonate.

Having determined the pattern of excretion for several days, we started administering the drug, giving 20-45 g of succus liquorice also divided into 8 equal parts daily. All the patients responded in the same way, though there were striking quantitative differences. As a rule the third specimen of urine was slightly, and the fourth definitely, smaller in amount than the corresponding specimens of previous days. The chloride output decreased accordingly. The excretion of urea plus ammonia did not decrease, nor did the urea clearance. No albumin or abnormality of urinary sediment was found in any of the cases. The blood-haemoglobin level

*Based on a lecture read before a combined meeting of the Association of Belgian Physicians and the Association of Dutch Physicians. The work was aided by a grant from the Dutch Foundation for Scientific Investigations.

fell appreciably, while the venous pressure, pulse pressure, and systolic pressure increased significantly. After a few days, intake and output were again in balance, but the patient had gained several kilograms in weight.

None of our nine intensively studied patients developed clinical oedema but some of the patients treated with liquorice for gastric ulcer, who were attending the outpatient department, had definite oedema of the legs.

Obviously the main effect of the drug was stimulation of the renal tubules to an excessive reabsorption of water and chlorides and probably also of sodium. Results of similar magnitude and nature were obtained

in a patient who received equivalent amount of product purified by dissolving the alcohol-soluble of succus liquoritiae in water and producing a precipitate by acidification. This precipitate was redissolved in water and ammonia and reprecipitated as a substance which consisted mainly of glycyrrhizin.

In another patient ammonium glycyrrhizate, from a wholesale dealer, produced a marked retention of extracellular fluid equal to that caused by the precipitated from a solution of succus liquoritiae by hydrochloric acid. On the other hand the filtrate when given in equivalent amounts to the

Fig. 1.—Three-hourly output of water, sodium, potassium, urea and creatinine in an ulcer patient during 54 days. Deoxycortone and especially liquorice produce a gain in weight, a positive sodium and chloride balance and a negative potassium balance, together with a decrease in haemoglobin and a rise in venous pressure, arterial pressure and pulse-pressure. Slight increase in blood-plasma chlorides and sodium, sharp fall in blood potassium. No influence on urea and creatinine.

was totally inactive. Therefore the oedema-producing factor is either glycyrrhizin or some substance related with it by acid.

COMPARISON WITH DEOXYCORTONE

effects observed were in all respects similar to following injection of large doses of deoxycortone. Injections of adrenocorticotrophic hormone (ACTH) now clear that succus liquoritiae and the purified extract contained a substance with an action resembling that of one of the two hormones and that this substance came when taken by mouth.

To gain more information, we studied in one case the excretion of sodium, potassium, and creatinine and varied the effect of a moderate and high dosage of deoxycortone with that of 20 and 45 g of succus liquoritiae daily.

Sodium and potassium in urine and food were determined by a flame photometer. Chloride was determined by the nitrate method of Laudat (1928) and in periods of high output by the method of Asper et al (1947), checking it

regularly by the silver nitrate method. Urea plus-ammonia was determined according to Ambard (Bots 1941), creatinine according to a modified Folin method, haemoglobin by the alkaline haematin method of Wu (1922) adapted to a photoelectric colorimeter, and total protein with the copper sulphate specific gravity method (Philips et al 1943). Venous pressure was determined by the standardised Lewis method according to Allen (1948), and Borst and Molhuysen (1950). The plasma volume was determined with Congo red, the disappearance curve being determined from 10 samples of blood taken 5-15 minutes after injection.

On the 2nd day of the observation period and on the 50th day (16 days after the withdrawal of drug therapy and 6 days after the withdrawal of the sodium and chloride supplement) the patient had the same weight. We assumed that he had also on these days exactly the same amount of potassium, sodium, and chloride in his body fluids. The average daily intake during these 49 days, based on food analyses, appeared to be (in milli equivalents) sodium 232, chloride 165, and potassium 113, and the average output was 220, 153, and 87.5 respectively. The extrarenal loss must therefore

Fig. 2—Six hourly output of water, sodium, chloride, potassium, urea, and creatinine in a patient with Addison's disease. Deoxycortone has a marked effect on weight, venous pressure, haemoglobin, and total protein, and a slight effect on electrolyte excretion. Liquorice has no effect or a slightly opposite one.

have been sodium 12, chloride 12, and potassium 25.5 m eq, the figures being of the magnitude that can be anticipated when the urine is carefully collected. To calculate the balance of the three electrolytes we assumed that not only the average, but also the actual, daily extra renal losses were 12, 12, and 25.5 m eq respectively. The results are presented in fig. 1. The patient happened to be a "strong reactor," and the effect of 20 g. of succous liquoritiae orally daily was quantitatively greater, though qualitatively the same, as that of two daily injections of 10 mg. deoxycortone. Both produced retention of water, sodium, and chloride, and this gave rise to the signs which overburdening of the circulation by extra

cellular fluid causes in the presence of a normal i.e., a fall in haemoglobin and serum protein, a rise in venous pressure, a rise in systolic pressure, very marked rise in pulse pressure, without a change in the pulse rate, pointing to a substantial increase in cardiac output. On Dec. 20, Jan. 25, and Feb. 1 the respective volumes were 2320, 2370, and 1980 ml., and the globin levels 14.5, 13.4, and 16.1 g. per 100 ml. figures show that the fall in haemoglobin truly an increase in plasma-volume. The usual increase in output of potassium by deoxycortone was also seen in this case, and

Fig. 1.—Effect of liquorice on water and chloride excretion, body weight, haemoglobin, venous pressure, arterial pressure, eosinophil-count and sedimentation-rate in a patient with rheumatoid arthritis. Effect of A.C.T.H. similar but more prompt and much stronger also prompt and strong response of eosinophils and sedimentation-rate.

t of deoxycortone was much exceeded by that of liquorice extract, which produced a strongly negative sodium balance. At the same time the sodium balance was strongly positive, which could not be fully accounted for by the increase in extracellular fluid shown by the increase in weight and by the retention of chloride, by the slight increase in the plasma sodium level, indicates that 450 m eq of potassium of the cells had been replaced by sodium. Ferrebee et al (1941), being unable to demonstrate the negative potassium balance and the positive sodium balance in dogs injected with 25 mg deoxycortone daily, found sodium replaced potassium in the muscles obtained by biopsy. As in Ferrebee's dogs, the potassium figures in the blood plasma of our patients receiving liquorice were much raised. The lowest value was 3.3 m eq per litre, in this patient, who was in bed, did not complain of any weakness. Unfortunately, electrocardiograms were not made.

During the treatment with liquorice no increase of weight could be obtained by injecting 10 mg deoxycortone daily. It is highly probable that this was because cardiac output was already greatly increased. An increase in cardiac output, unless accounted for by an increase in metabolism, is always followed by a rise in the urinary output of the three components of extracellular fluid (Borst 1938, 1941, 1948; Borst and de Vries 1950). Hence, in subjects with normal heart and kidneys, the increase of extracellular fluids during long continued treatment with deoxycortone or succus liquoritæ is self-limiting. The diuretic effect, postulated by several authors (Silvette and Britton 1938, Rigan et al 1940, Ferrebee et al 1941, Mahnos et al 1941, Gaunt et al 1949, Roemmelt et al 1949) as due to the continued deoxycortone injections, and even leading to "diabetes insipidus," can be explained by this mechanism.

There are a few differences in the effect of deoxycortone and succus liquoritæ. After discontinuing deoxycortone treatment, the rebound is very pronounced and starts within 24 hours of the last injection. Discontinuance of succus therapy is not followed by so impressive a rebound as 10 days before the weight, hæmoglobin, and venous pressure are on the pre-treatment level, indeed, the blood pressure remained high so long as the sodium supplement to the diet was given. The retention of potassium, starting gradually after discontinuing succus therapy, becomes almost complete in the next 5 days.

COMPARISON WITH A.C.T.H.

The above observations did not enable us to decide whether the action of the succus resembled that of deoxycortone or of A.C.T.H., all the signs and symptoms observed in our patients can be produced by either hormone.

Accordingly we started the treatment with succus in a patient with Addison's disease. His diet was not so rigidly standardised, but we supplied daily exactly the same type of meals and fluids in the same quantities. The food was prepared without salt. The succus was of the same batch and was prepared on the same day and mixed with sodium bicarbonate and sodium chloride as in the first patient. The findings are shown in fig. 2. The patient had been on a daily injection of 2 mg of deoxycortone for a year. After changing deoxycortone dissolved in oil to an injection of pure oil, there was no definite increase in the output of water, sodium, and chloride, nor was potassium output increased. There must nevertheless have been a slightly negative balance of extracellular fluid, for his weight went down. More pronounced and also prompt was the drop of the blood plasma volume, as shown by the rise in the level of hæmoglobin and especially the fall in venous pressure. Then 20 g of succus was given daily for 6 days, the dose being later increased to 45 g a day. Response to the

treatment was not apparent, if there was any, it was negative. After withdrawal of the drug, weight and plasma volume slightly increased.

As it was possible that succus liquoritæ only enhances the effect of the sodium conserving hormones of the adrenals, deoxycortone and liquorice were then given simultaneously. First 2 mg of deoxycortone, and then 5 mg, was injected daily and after equilibrium had been established, liquorice was added for 3 days. Deoxycortone produced a slight retention of chloride and sodium, the rise in weight and especially the fall in hæmoglobin and total proteins and the rise in venous pressure were striking. The liquorice was again devoid of effect, there was even evidence that it was harmful. Finally succus was given for a third period, and after 2 days we discontinued injections of deoxycortone, the patient continuing with succus only. This time the effect of the withdrawal of hormone therapy was unimpressive, not only venous pressure, serum protein, and hæmoglobin reacted promptly, but also there was a significant increase in the output of chloride and especially of sodium, leaving no doubt of the total ineffectiveness of succus liquoritæ in correcting the disturbance in the metabolism of water and electrolytes in this case of adrenal insufficiency.

Though the patient could live on a normal diet without deoxycortone injections, he did not respond to A.C.T.H. either. We injected 25 mg of A.C.T.H. from a batch that had proved to be very active in other patients. There was no change in electrolyte or uric acid excretion, nor was there the slightest fall in eosinophil count (data not in figure).

Though we had observed patients with gastric ulcer who did not respond so strongly to succus as the patient whose data are presented in fig. 1, we never saw a total absence of effect or a slightly negative effect as in the patient with Addison's disease. This suggested that the action of succus liquoritæ is mediated by the adrenals.

To determine whether the drug has a complete A.C.T.H. action a patient with chronic rheumatoid arthritis was treated with the remedy. It was a typical case of two years' duration, three courses of gold injections given in the department for rheumatic diseases had met with only temporary success. All the joints of both the patient's hands were swollen, and he could not reach a glass of water from his side table without help. There was a stiffness of arm and shoulder, hampering all movement. The knee joints were swollen, and fluid could easily be demonstrated. Treatment with amidopyrine 0.5 g three times daily brought some improvement, though the sedimentation rate did not decrease significantly. Amidopyrine was next replaced by acetylsalicylic acid 0.5 g three times daily, and then all treatment was discontinued. Three days later we started with 45 g of succus daily, stiffness being at its worst at that time. After 33 hours the patient thought there was some improvement and declared that he was as well as under treatment with amidopyrine. Objectively, however, the results were not impressive, though he could move a little better. His grip was not improved when measured by ergometer. Injections of ascorbic acid, given with succus treatment, were without effect.

The retention of water and sodium chloride was not as striking as in the patient with gastric ulcer described above, but there was a definite decrease in chloride and water output and the other signs of retention of extracellular fluid were also present (see fig. 3). Withdrawal of the drug was followed by a negative water and chloride balance and also by a decrease in venous pressure. At this time the patient was complaining of a severe exacerbation of his disease, and was completely incapacitated, but after a few days there was some improvement. Then we started with A.C.T.H., the first injection being 25 mg. After 6 hours he could sit unassisted, move his arms

have been sodium 12, chloride 12, and potassium 25.5 m eq., the figures being of the magnitude that can be anticipated when the urine is carefully collected. To calculate the balance of the three electrolytes we assumed that not only the average, but also the actual, daily extra renal losses were 12, 12, and 25.5 m eq. respectively. The results are presented in fig. 1. The patient happened to be a "strong reactor," and the effect of 20 g of succus liquoritæ orally daily was quantitatively greater, though qualitatively the same, as that of two daily injections of 10 mg deoxycortone. Both produced retention of water, sodium, and chloride, and thus gave rise to the signs which overburdening of the circulation by extra

cellular fluid causes in the presence of a normal i.e., a fall in hæmoglobin and serum protein, a rise in venous pressure, a rise in systolic pressure, very marked rise in pulse pressure, without a change in the pulse rate, pointing to a substantial increase in cardiac output.

On Dec 20, Jan 25, and Feb 1 the respective plasma volumes were 2320, 2370, and 1980 ml, and the hæmoglobin levels 14.5, 13.4, and 16.1 g per 100 ml. These figures show that the fall in hæmoglobin truly reflected an increase in plasma volume.

The usual increase in output of potassium produced by deoxycortone was also seen in this case, but the

Fig. 3—Effect of liquorice on water and chloride excretion, body weight, hæmoglobin, venous pressure, arterial pressure, eosinophil-count, and sedimentation-rate in a patient with rheumatoid arthritis. Effect of A.C.T.H. similar but more prompt and much stronger; also prompt and strong response of eosinophils and sedimentation-rate.

of deoxycortone was much exceeded by that of succus extract, which produced a strongly negative sodium balance. At the same time the sodium was strongly positive which could not be accounted for by the increase in extracellular fluid shown by the slight increase in weight and by the retention of chloride. The slight increase in the plasma-sodium level indicates that 450 m.e. of potassium of the cells has been replaced by sodium. Ferrive et al. (1941) are unable to demonstrate the negative potassium balance and the positive sodium balance in dogs on a diet of 25 mg deoxycortone daily, found sodium replaced potassium in the muscles obtained by biopsy. As in these dogs the potassium figures in the blood of our patients receiving liquorice were much raised. The lowest value was 3.3 m.e. per litre. This patient was in bed did not complain of weakness. Unfortunately, electrocardiograms were not made.

During the treatment with liquorice no increase of fluid could be obtained by injecting 10 mg deoxycortone daily. It is highly probable that this was because cardiac output was already greatly increased. An increase in cardiac output, unless accounted for by an increase in metabolism, is always followed by a rise in urinary output of the three components of extracellular fluid (Borst 1933, 1941; Bors and de Vries 1939). Hence in subjects with normal heart and kidneys, increase of extracellular fluids during long-continued treatment with deoxycortone or succus liquorice is self-limiting. The diuretic effect postulated by several workers (Silvete and Britton 1938; Pagan et al. 1940; Ferrive et al. 1941; Malinos et al. 1941; Gaunt et al. 1942; Poemmel et al. 1949) as due to the continued corticoid injections, and even leading to 'diabetes pidus' can be explained by this mechanism.

There are a few differences in the effect of deoxycortone and succus liquorice. After discontinuing deoxycortone treatment, the rebound is very pronounced and starts in 24 hours of the last injection. Discontinuance of therapy is not followed by so impressive a rebound. 10 days before the weight, haemoglobin and venous pressure are on the pre-treatment level, indeed, the blood pressure remained high so long as the sodium element to the diet was given. The retention of sodium, starting gradually after discontinuing succus liquorice, becomes almost complete in the next 5 days.

COMPARISON WITH A.C.T.H.

The above observations did not enable us to decide whether the action of the succus resembled that of deoxycortone or of A.C.T.H., all the signs and symptoms observed in our patients can be produced by either.

Accordingly we started the treatment with succus in a patient with Addison's disease. His diet was not so strictly standardised, but we supplied daily exactly the same type of meals and fluids in the same quantities. The food was prepared without salt. The succus was of the same batch and was prepared on the same day and mixed with sodium bicarbonate and sodium chloride as in the first patient. The findings are shown in fig. 2. The patient had been on a daily injection of 2 mg of deoxycortone for a year. After changing deoxycortone dissolved in oil to an injection of pure oil, there was no definite increase in the output of water, sodium, and chloride, nor was potassium output increased. There must nevertheless have been a slightly negative balance of extracellular fluid, for his weight went down. More pronounced and also prompt was the drop of the blood-plasma volume, as shown by the rise in the level of haemoglobin and especially the fall in venous pressure. Then 20 g of succus was given daily for 6 days, the dose being later increased to 45 g a day. Response to the

treatment was not apparent if there was any, it was a curve. After withdrawal of the drug weight and plasma volume sharply increased.

As it was possible that succus liquorice only enhanced the effect of the sodium-retaining hormones of the adrenal glands, deoxycortone and liquorice were then given in combination. First 2 mg of deoxycortone, and then 2 mg was injected daily and after equilibrium had been established liquorice was added for 3 days. Deoxycortone produced a slight retention of chloride and sodium, the rise in weight and especially the fall in haemoglobin and to a degree the rise in venous pressure were striking. The liquorice was again devoid of effect, there was even evidence that it was harmful. Finally succus was given for a third period and after 2 days the patient was on a mixture of deoxycortone and succus continuing with succus only. This time the effect of the withdrawal of hormone therapy was impressive, not only venous pressure, serum protein and haemoglobin dropped promptly but also there was a significant increase in the output of chloride and especially of sodium leaving no doubt of the total ineffectiveness of succus liquorice in correcting the disturbance in the metabolism of water and electrolytes in this case of adrenal insufficiency.

Though the patient could live on a normal diet without deoxycortone injections he did not respond to a C.T.H. either. We injected 25 mg of A.C.T.H. from a batch that had proved to be very active in other patients. There was no change in electrolyte or urine acid excretion nor was there the slightest fall in eosinophil-count (data not in figure).

Though we had observed patients with gastric ulcer who did not respond so strongly to succus as the patient whose data are presented in fig. 1 we never saw a total absence of effect or a slightly negative effect as in the patient with Addison's disease. This suggested that the action of succus liquorice is mediated by the adrenals.

To determine whether the drug has a complete A.C.T.H. action a patient with chronic rheumatoid arthritis was treated with the remedy. It was a typical case of two years' duration, three courses of gold injections given in the department for rheumatic diseases had met with only temporary success. All the joints of both the patient's hands were swollen and he could not reach a glass of water from his side-table without help. There was a stiffness of arm and shoulder hampering all movement. The knee joints were swollen, and fluid could easily be demonstrated. Treatment with amidopyrine 0.5 g three times daily brought some improvement, though the sedimentation rate did not decrease significantly. Amidopyrine was next replaced by acetylsalicylic acid 0.5 g three times daily, and then all treatment was discontinued. Three days later we started with 45 g of succus daily, stiffness being at its worst at that time. After 33 hours the patient thought there was some improvement and declared that he was as well as under treatment with amidopyrine. Objectively, however, the results were not impressive, though he could move a little better. His grip was not improved when measured by ergometer. Injections of ascorbic acid given with succus treatment, were without effect.

The retention of water and sodium chloride was not as striking as in the patient with gastric ulcer described above, but there was a definite decrease in chloride and water output and the other signs of retention of extracellular fluid were also present (see fig. 3). Withdrawal of the drug was followed by a negative water and chloride balance and also by a decrease in venous pressure. At this time the patient was complaining of a severe exacerbation of his disease and was completely incapacitated, but after a few days there was some improvement. Then we started with A.C.T.H., the first injection being 25 mg. After 6 hours he could sit unassisted, move his arms

freely, take things from the side table, and eat without help. The situation did not change as long as ACTH was given, but 2 days after the last injection of the pituitary hormone all the incapacitating symptoms came back. After another 4 days liquorice treatment was resumed. This time there was not even any subjective improvement, though the effect on the electrolytes was as usual, and potassium in the blood fell to 3.4 m eq per litre (data not included in fig 3). Uric acid excretion, which had increased by 25% during ACTH treatment, was unchanged.

The effect of ACTH on water and electrolyte balance was much greater than the effect of succus, but the resemblance to the response of a strong reactor to succus, as demonstrated in fig 1, is clear. The retention of sodium and chloride is more complete after ACTH, but the same tendency to establish a new balance as a result of the increased blood volume, venous pressure, and cardiac output is demonstrated by the increase of chloride and sodium excretion on the 4th day of treatment. There is, however, a difference in the prompt rebound after discontinuance of ACTH injections. The increase in the output of potassium with ACTH is lacking, but there is a retention during the "rebound". On the day we started the first course of liquorice there was a sharp, unexplained rise in the eosinophils, followed by a gradual decline that turned into a gradual rise after the treatment was stopped. ACTH brought the number down to virtually nil within 6 hours of the first injection. The rebound came 36 hours after the last injection. Resumption of liquorice was not followed by a definite decline. The sedimentation rate (Wintrobe), which had been continuously over 100 mm in one hour in the 4 weeks before treatment with succus, showed during the use of the drug a downward trend which was not very pronounced and could not compare with the results of ACTH treatment. The second time the same tendency towards lower figures was not observed, but there was again a rise after withdrawal of the drug.

It may be that strong reactors would have shown a greater fall in eosinophils and sedimentation rate, and a more definite improvement. In three students, following the use of 30 g of succus, a fall in eosinophils of nearly 20% was found, being most marked 36 hours after the succus had been taken, but not exceeding spontaneous short lasting fluctuations seen in the same subjects. It may be that they were weak reactors for none had shown the considerable gain in weight that Revers regularly saw in specially sensitive subjects, even after the use of smaller quantities of succus.

SOME QUESTIONS

Many questions remain to be answered

- 1 What is the active principle of succus liquoritiae?
- 2 Are the differences in response due to differences in destruction by the juices of the digestive tract, to differences in absorption, or to considerable differences in individual sensitivity to the drug?
- 3 Can succus or the active principle, be given without harm by injection, and what will be the effect?
- 4 Is the deoxycortone like effect seen in eight subjects with intact adrenals but totally absent in a patient with Addison's disease, the result of stimulation of the adrenals? If it is why is the influence of liquorice extract on eosinophils and uric acid excretion, and on the symptoms of a patient with rheumatoid arthritis negligible or absent?
- 5 Is the output of 17 ketosteroids substantially increased in patients who react to the use of liquorice by a considerable retention of extracellular fluid?

Some of these problems raise again the question of the existence and function of cortical adrenal hormones with a pure deoxycortone like action, which, unlike 'Cortisone' and Compound F, do not affect carbohydrate

metabolism, influence eosinophils and uric acid, or rheumatoid arthritis.

SUMMARY

1 Observations of Revers that in a certain proportion of normal people liquorice medication followed by oedema are confirmed.

2 Even when no clinical oedema developed, the use of the drug resulted in retention of water, and chloride. Hemoglobin and total serum protein decreased, venous pressure, blood pressure, and pulse pressure rose considerably, and the output of potassium was much increased. The results were consistent in nine subjects with normal adrenals.

3 In a patient in whom the sodium and potassium balance was determined, a replacement of 450 mEq of intracellular potassium by an equal amount of sodium could be shown. The blood potassium level fell to 3.4 m eq per litre.

4 The harmful effect (especially in the elderly) of potassium loss on the myocardium, which is overburdened by the increased venous pressure and by the considerable rise in blood pressure, is emphasised. The occurrence of cardiac asthma in subjects using liquorice in sweets or in drugs is fully explained.

5 The effect of a liquorice extract by mouth is almost all respects similar to that of injections of large doses of deoxycortone, but it lasts longer. The blood pressure tends to remain raised after discontinuance of the drug, unless a salt free diet is given.

6 In subjects with normal heart and kidneys the retention of water and sodium chloride during treatment with deoxycortone, ACTH, or succus liquoritiae is so limiting, because the rise in venous pressure leads to an increase in cardiac output, which induces a salt diuresis.

7 A patient with Addison's disease not responding to ACTH did not respond positively to succus liquoritiae. Indeed there was a slight negative response.

8 A patient with rheumatoid arthritis responded favourably to ACTH showed only a negligible improvement, or none, after the use of succus liquoritiae.

We are indebted to head nurses A. van Putten and W. L. Sipkes, to Miss E. Knol, and to the technicians Misses J. Daakselaar, L. Quelle, E. Mollema, R. Buitenhuys, F. Welthof, and D. Doyer, for invaluable assistance.

DIAGNOSTIC VALUE OF INCREASED URINARY OUTPUT OF ADRENALINE AND ADRENALINE IN PHEOCHROMOCYTOMA

ENGEL
M.D.

U S VON EULER
M.D.

1 MEDICAL WARD, PROFESSOR OF PHYSIOLOGY
HOSPITAL, FALUN FACULTY OF MEDICINE, STOCKHOLM

diagnosis of pheochromocytoma is still considered intricate and difficult, in spite of several recent contributions such as the histamine and benzodioxane (Roth and Kvale 1945; Goldenberg et al 1948). A demonstration of an increased production of methyl active catechol derivatives which should form a basis for a rational diagnosis, has hitherto not been published.

It has been shown that adrenaline and other catechol amines, when administered to man, are partly excreted through the urine in a conjugated form presumably as sulphate esters (Richter 1940). A certain amount of catechol derivatives is also normally secreted through urine, as shown by Holtz et al. in 1947 (uroseripathin) was supposed to consist of a mixture of hydroxy-amine, adrenaline, and noradrenaline.

Since catechol derivatives may be extracted from urine and estimated quantitatively in a comparatively simple way (Euler and Hellner 1950) it appeared that an increased formation and output of such substances could be used as a basis for the diagnosis of pheochromocytoma. After acid hydrolysis of the urine and adsorption on silica, the catechols in normal urine could be shown, by biological estimation, to consist largely of noradrenaline (Euler 1948-49; Euler and Hellner 1950; Kroneberg and Schumann 1950). In two suspected cases of pheochromocytoma observed in the medical ward of the County Hospital of Falun the urine was subjected to catechol estimation by the technique of Euler and Hellner (1950).

Case 1—A woman born 1901. Albuminuria at 13 after a common cold and in connection with her three pregnancies. High blood pressure noted 1935-36 when treated at a psychiatric hospital. Glucosuria 1947. Attacks of tachycardia, pallor and vomiting on five occasions since September, 1948. During the last two observed attacks the blood pressure fell from about 250 to 125 mm Hg systolic. Basal metabolic rate (B.M.R.) constantly high, maximally - 155%. Fasting blood-sugar maximally 358 mg per 100 ml. Glucosuria at intervals. No acidosis or polyuria.

Case 2—A woman born 1906. Complained of palpitations at night when examined in March 1948. B.P. 170/110. One year later re-examination and suggestion of thyrotoxicosis. B.M.R. - 144-150%. Hyperglycaemia and altered glucose tolerance test. B.P. during time of observation at hospital in 1949 165-200 systolic and 110 diastolic. No paroxysmal spells of hypertension observed.

The following figures illustrate the results of urine analysis

Case	Date 1950	Urinary adrenaline (µg per 24 hours)	Urinary noradrenaline (µg per 24 hours)	Percentage of adrenaline in total
1	Jan 13	15	543	2.7
	Feb 20	54	1240	4.0
	March 8	21	973	2.2
2	Jan. 20	250	117	69
	Feb 20	80	780	9.4
	April 10	110	223	33

Compared with the normal urinary noradrenaline/adrenaline output of 20-40 µg. per day, the figures were very greatly increased in these two cases, indicating catechol-producing tumours. Operation was performed in case 1 on March 14 and in case 2 on April 11 (Dr Tolagen). In the first case a tumour weighing 48 g was

removed situated at the bifurcation of the abdominal aorta. Histological examination showed a typical pheochromocytoma. It contained 4.5 mg per g of noradrenaline and less than 0.05 mg per g of adrenaline. In the second case a tumour weighing 20 g was removed from the left suprarenal. Malignancy could not be excluded. It contained 0.75 mg per g of adrenaline and 0.75 mg per g of noradrenaline. The relative contents of the catechols in the two tumours were also borne out by paper-chromatography.

It is noteworthy that the proportions of noradrenaline and adrenaline in the urine were approximately the same as in the tumours. As in the cases of Holton (1949) and Goldenberg et al. (1949), the relative amount of catechols in the tumours showed wide variations.

After removal of the tumours the catechol output in urine fell quickly to normal in both cases.

SUMMARY

By estimating the total output of noradrenaline and adrenaline in the urine a reliable diagnosis of pheochromocytoma may be obtained. This is illustrated by observations on two cases successfully treated by operation and histologically verified.

QUEEN ELIZABETH HOSPITAL, BIRMINGHAM

The report by Nissim (1947) of an effective preparation of iron which could safely be injected intravenously led us to search for examples of the rare refractory type of hypochromic anemia, which though resistant to iron by mouth will respond to the intravenous injection of organic iron compounds (Slack and Wilkinson 1949). Little is known about the cause of the refractoriness, and it remains to be shown whether there are differences in the clinical manifestations or in the morphology of the blood which will distinguish the refractory type from other iron deficiency anemias.

SELECTION OF CASES

There are many reasons why a hypochromic anemia may appear to be refractory to iron by mouth, so the following criteria must be satisfied before this can be established.

- 1 A potent preparation of iron must have been used.
- 2 Full dosage must have been taken and tolerated for an adequate period.
- 3 The presence of hemorrhage, chronic infection, renal failure and hypoplasia must have been excluded.

Our patients had received ferrous sulphate gr 10 t.d.s. by mouth for at least eight weeks without there being any significant rise in the red cell count or hemoglobin values. Precautions had to be observed to

ensure that ferrous sulphate was indeed the preparation taken, since other patients responded satisfactorily to iron by mouth when ferrous sulphate was substituted for the proprietary preparations previously prescribed, some of which are known to contain inadequate quantities of iron. The patient's statement that his faeces had become dark was accepted as an indication that iron had been taken, because it takes at least gr 10 of ferrous sulphate daily to change the colour of the faeces. Absence of vomiting and diarrhoea was regarded as evidence of tolerance of iron. Finally, all these patients were admitted to hospital for varying periods before intravenous therapy, so that infection, renal failure, and excessive blood loss could be excluded and bone-marrow films examined.

Six truly refractory cases were found—five women and one man. All these patients had defective fat absorption, as shown by abnormal fat balance tests (Cooke et al 1946), and X ray examination of the small intestine showed evidence of a "deficiency pattern". Our purpose here is to draw attention to the association of refractory hypochromic anæmia with steatorrhœa.

HEMATOLOGY

Peripheral blood films in four of these cases were typical of hypochromic anæmia associated with steatorrhœa (Bennett et al 1932). The red cells showed considerable variation in depth of staining, with conspicuous anisocytosis and moderate poikilocytosis. In general the smaller erythrocytes were hypochromic, whereas the larger cells were often normochromic and in four cases were obviously macrocytic, the so called dimorphic picture. Target cells were present in various numbers in four cases. In cases 1 and 5 Price Jones curves showed the mean cell diameters to be 7.38 μ and 7.95 μ . In the remaining two patients, one of whom possibly had chronic pancreatitis, the peripheral blood picture was indistinguishable from that of idiopathic hypochromic anæmia.

Sternal marrow was examined in five of the six patients, and all showed erythroblastic hyperplasia, in which there was a variable mixture of small deformed iron deficiency normoblasts and large atypical normoblasts. The small deformed normoblasts appeared identical with those seen in idiopathic iron deficiency anæmias, whereas the larger forms were intermediate in size between typical normoblasts and megaloblasts, were prematurely hemoglobinised, and at the polychromatic stage did not show the same degree of condensation of nuclear chromatin as in typical normoblasts at the same stage of development (Cooke et al 1948). These larger normoblasts closely resembled those considered by Israëls (1941) to indicate intermediate erythropoiesis. The reticulocytes in all the cases were within normal limits.

TREATMENT

Iron was given intravenously in the form of 'Ferrovenin,' containing 100 mg in 5 ml. The initial dose was 20 mg, this was followed by 60 mg and then repeated doses of 100 mg until the estimated total dosage was reached.

Inpatients (three cases) received injections daily and outpatients twice weekly. Reactions to the treatment were slight, the worst being a severe lower backache, coming on suddenly 3-4 minutes after the injection and radiating round both sides of the abdomen for a few seconds. This occurred in three cases on several occasions and may have been of renal origin. Thrombosis of veins followed only 2 out of 130 injections.

CASE RECORDS

Case 1—A man aged 51. Insidious onset of diarrhoea in 1935, with bulky, pale, slimy stools, aggravated by fatty food, followed by a severe attack in 1936. Gastrojejunostomy performed in 1937 for pyloric stenosis from duodenal ulcer. No further dyspepsia but loose stools continued. In bad health for last 14 years with loss of weight, weakness and fainting turns, difficulty in swallowing, sore tongue, and erythematous papular rash at pressure points. Bleeding piles cured by

injection in 1936, no other evidence of blood loss. Counts showed hypochromic anæmia continuously with no response to iron by mouth. Took ferrous sulphate and ferric and ammonium citrate in large doses every year from 1940 to 1949 but with no rise in Hb or significant change in mean corpuscular hemoglobin concentration (25%). Ascorbic acid, liver preparations, and folic acid had no effect, and from 1944 he was admitted twice yearly for massive blood transfusions. With this treatment he could just manage to do work as an accountant.

He had observed koilonychia of his fingers and toes in many years. The hollows were unaffected by iron by mouth but became more shallow after blood transfusion and disappeared as the anæmia responded to intravenous iron.

On admission, he was thin and asthenic, height 5 ft., weight 9 st 2 lb, no sign of organic disease apart from anæmia.

Investigations—Fat absorption 60-85%. Fractional test meal showed histamine fast achlorhydria. Glucose tolerance test normal. Blood proteins 5.6 g per 100 ml (albumin/globulin ratio normal). Van den Bergh reaction negative. Blood calcium and cholesterol normal. X ray films of chest normal.

Response to Treatment—This was a case of hypochromic anæmia, closely observed for 14 years, which had not responded to ferrous sulphate by mouth, given on numerous occasions as an inpatient and outpatient. There was a good response to 19 g of iron intravenously, but a macrocytic anæmia appeared and has remained constant for a year with a further treatment. The steatorrhœa may have resulted from the gastrojejunostomy but probably preceded it.

Case 2—A woman aged 31. Chronic lassitude, worse since birth of baby three years previously, with sore tongue and cracked lips for many years, and some difficulty in swallowing solids. Loose stools all her life, 2-4 times daily, pale and porridge like. No abnormal blood loss. Idiopathic steatorrhœa was diagnosed from a blood film before a dental extraction.

On admission she was small and slightly built, height 4 ft 11 in, weight 7 st 1 lb. Well marked pallor of mucous membranes. Angular stomatitis and atrophic tongue, without ulceration. No koilonychia or finger clubbing. General examination normal.

Investigations—Fat absorption 70% and flat chylomicron-graph. Fractional test meal showed low acidity. Glucose tolerance curve normal. Blood proteins 7.9 g per 100 ml (albumin/globulin ratio normal). Serum calcium and serum phosphorus normal. No radiological evidence of osteoporosis.

Response to Treatment—This woman had probably suffered from a hypochromic anæmia most of her life.

Fig 1—Response to intravenous iron in

fusion. With this treatment he could just manage to do work as an accountant.

He had observed koilonychia of his fingers and toes in many years. The hollows were unaffected by iron by mouth but became more shallow after blood transfusion and disappeared as the anæmia responded to intravenous iron.

On admission, he was thin and asthenic, height 5 ft., weight 9 st 2 lb, no sign of organic disease apart from anæmia.

Investigations—Fat absorption 60-85%. Fractional test meal showed histamine fast achlorhydria. Glucose tolerance test normal. Blood proteins 5.6 g per 100 ml (albumin/globulin ratio normal). Van den Bergh reaction negative. Blood calcium and cholesterol normal. X ray films of chest normal.

Response to Treatment—This was a case of hypochromic anæmia, closely observed for 14 years, which had not responded to ferrous sulphate by mouth, given on numerous occasions as an inpatient and outpatient. There was a good response to 19 g of iron intravenously, but a macrocytic anæmia appeared and has remained constant for a year with a further treatment. The steatorrhœa may have resulted from the gastrojejunostomy but probably preceded it.

Case 2—A woman aged 31. Chronic lassitude, worse since birth of baby three years previously, with sore tongue and cracked lips for many years, and some difficulty in swallowing solids. Loose stools all her life, 2-4 times daily, pale and porridge like. No abnormal blood loss. Idiopathic steatorrhœa was diagnosed from a blood film before a dental extraction.

On admission she was small and slightly built, height 4 ft 11 in, weight 7 st 1 lb. Well marked pallor of mucous membranes. Angular stomatitis and atrophic tongue, without ulceration. No koilonychia or finger clubbing. General examination normal.

Investigations—Fat absorption 70% and flat chylomicron-graph. Fractional test meal showed low acidity. Glucose tolerance curve normal. Blood proteins 7.9 g per 100 ml (albumin/globulin ratio normal). Serum calcium and serum phosphorus normal. No radiological evidence of osteoporosis.

Response to Treatment—This woman had probably suffered from a hypochromic anæmia most of her life.

Fig 2—Response in case 2.

sulphate gr 10 t d s was given by mouth for 8 weeks without effect, and molybdenised iron, folic acid, polysed liver, were also ineffective. Ferrivenin to a 168 g intravenously restored her Hb to normal, a macrocytosis which has since remained unaltered 6 months without further treatment. Her tongue to be atrophic or sore. She said that she now knew first time the feeling of being well.

3—A woman aged 57. Normal childhood, but severe with weakness and dyspnoea at age of 13. Adult characterised by many years of abdominal complaints, early pain, flatulence, and occasional diarrhoea. In 1914 appendectomy and removal of gall bladder and multiple stones. Some improvement of dyspepsia, but further symptoms occurred and in 1933 gastrostomy was done for pyloric stenosis from duodenal ulcer. Since then has never felt fit, owing to weakness and occasional vomiting. Severe hypochromic anaemia was found in 1944, responded slowly to iron by mouth. This treatment has been continued, but since 1947 she has gradually become more anæmic and has developed sore tongue, flatulence, indigestion, and pins and needles. She has been faint at times. Her bowels have opened 2-4 times daily. Attacks of diarrhoea, when motions were pale and ve.

On admission she was pale and thin, height 5 ft 4 in, weight 7 st 10 lb. Atrophic tongue and brittle nails, but no signs of organic disease.

Investigations—Fat absorption 83-86%. Histamine fast negative. Blood proteins 6 g per 100 ml (albumin/globulin ratio normal). Liver function tests normal. Van den Bergh reaction negative.

Fig 3—Response in case 3

rapidly returned to normal with ferrivenin (2 g of iron). Macrocytosis, with mean corpuscular volume (M.C.V.) c. μ , developed after 2 months.

Case 4—A woman aged 31. Suffered from vomiting and diarrhoea in infancy and nearly died when 1 year old. Child then healthy apart from anaemia at 14, treated with iron and liver but malaise and fatigue continued. Anaemia noticed in 1944 when Hb was 45% and she received iron. In 1946 was admitted to hospital with a swinging temperature ascribed to "unresolved pneumonia". Severe anaemia found, and haematologist suggested possibility of steatorrhoea. Bowels usually regular, but liable to attacks of diarrhoea and small painful ulcers on tongue. In 1946 had right pleural effusion with area of tubercle infiltration in lung. Long illness ensued, complicated by colic, pyelitis and phlebitis in both legs. In next 3 years health was handicapped by persistent anaemia. No blood loss.

On admission she was thin, pale, and asthenic, height 6 in., weight 8 st 4 lb. Tongue normal. No koilonychia. Chronic painful ulcer, 1 inch in diameter on inner left ankle said to have been present for 2 1/2 years.

Investigations—Fat absorption 65-77%. Fractional test-negative. Hydrochloric acid only after histamine. Flat glucose tolerance curve. Serum proteins 6.8 g per 100 ml

(albumin/globulin ratio normal). Serum calcium and serum phosphorus normal. Van den Bergh reaction negative. Liver function tests normal. X-ray film of chest showed small area of fibrosis only.

Response to Treatment—This was a case of idiopathic steatorrhoea with a dimorphic blood picture, giving a low colour index in spite of the high mean cell volume. The anaemia did not respond to iron by mouth over many years, but 28 g of iron intra-

Fig 4—Response in case 4

venously produced a reticulocytosis of 22% and a temporary increase of macrocytosis and raised the Hb to normal levels.

Case 5—A woman aged 38. Had infantile diarrhoea lasting 24 weeks from age of 3 months. Later had recurrent episodes of vomiting and diarrhoea for 24 hours in otherwise normal childhood. No history of steatorrhoea in family. Father, mother, and one sister died of tuberculosis. In adult life she was

well until first pregnancy, at age of 30 when she developed stomal ulcers and diarrhoea, which continued intermittently for next 3 years before anaemia was discovered and steatorrhoea diagnosed. In last 5 years had further attacks of diarrhoea, lasting up to 6 weeks, with large offensive porridge-like motions, attacks often follow colds and chilling and are often premenstrual accompanied by flatulence, anorexia and abdominal discomfort. She has lost weight and had recurrent soreness of tongue.

On admission she was pale and thin, height 5 ft 3 in, weight 7 st. Tongue normal. No koilonychia. No signs of organic disease.

Investigations—Fat balance 79%. Low gastric acidity. Flat glucose tolerance curve. Van den Bergh reaction negative. Serum sodium, calcium, and phosphorus normal. Blood proteins 7 g per 100 ml (albumin/globulin ratio normal). X-ray films of chest normal.

Response to Treatment—This was a typical case of idiopathic steatorrhoea which had not responded to iron by mouth given for 18 months. Outpatient treatment with ferrivenin

(228 g of iron) raised her Hb to 96% and produced a macrocytosis (M.C.V. 105.5 c μ).

Case 6—A nursing sister aged 50. With a refractory hypochromic anaemia under careful observation for 14 years. No response to any preparation of iron by mouth in spite of additional ascorbic acid. Ferrous sulphate 2 g daily taken continuously for many years. Plexan also taken. Symptoms were malaise, excessive dyspnoea on exertion, nocturnal cramps in legs, and occasional sore tongue. Had cholecystectomy.

L 2

for gall stones in 1930, since then had recurrent attacks of upper epigastric pain with continuous vomiting lasting 2-3 days, suggestive of chronic pancreatitis. Bowels usually opened 2-3 times daily, but had frequent attacks of diarrhoea with bulky pale motions.

On admission she was pale but well nourished, height 5 ft 4½ in, weight 8 st 8 lb. Koilonychia present. Tongue normal.

Investigations—Fat absorption—85%. Normal gastric acidity and glucose tolerance. Blood proteins 6 g per 100 ml (albumin/globulin ratio normal). Van den Bergh reaction negative. Blood

calcium normal. X ray films of chest and abdomen normal.

Response to Treatment—This patient's hypochromic anaemia had never responded to iron by mouth, and in view of our previous experience, a fat balance test was performed and she was found to have steatorrhoea, possibly due to chronic pancreatitis. Daily injections of intravenous iron to a total of 2 g relieved her malaise and nocturnal cramps and improved her energy, but her dyspnoea on exertion remains. Her blood counts have returned to normal, but, up to 2 months after the course of treatment, there has been no macrocytosis.

Fig. 7—Rate of regeneration of haemoglobin in response to iron by mouth: 1, normal (Heath 1933), 16, in steatorrhoea (2 is almost completely refractory, and 3-6 are partially refractory).

rates of regeneration were similar to those reported elsewhere (Goetsch et al 1946). The maximum rate of haemoglobin regeneration was 0.25 g daily, calculated at weekly intervals, and the minimum, seen in a patient who received injections twice weekly, was 0.04 g. In the three cases where the reticulocyte response could be followed the "peaks" were higher than with iron by mouth and in one the peak was 23%, compared with the expected value of 8% (Mint and Heath 1932).

These patients have been under observation for 6-18 months, and so far further iron has not been necessary. A striking feature of the results has been the rapid improvement in the mean corpuscular haemoglobin concentration and the pronounced increase in the mean cell volume, associated with obvious macrocytosis in the peripheral blood films, in five out of the six patients.

DISCUSSION

If radioactive iron is injected intravenously (Finch et al 1949), 75% will be incorporated into the erythrocytes within ten days, the remaining 25% being mainly stored. There seems to be a reciprocal relationship between the amount of intravenous iron utilised and the quantity stored, and it is the uncertainty of the state of the existing stores at any given time that prevents any accurate estimation of the amount needed by the

Fig. 6—Response in case 6.

SUMMARY OF RESULTS

The six cases all responded satisfactorily, and the results are shown graphically in figs 1-6. The actual

body. It has been assumed that 25 mg of iron will produce a rise of haemoglobin of 1% (Scott 1949). In this series the total amount of iron was up to twice that needed to bring the blood to normal.

There has been little work reported on the refractory hypochromic anaemia. Powell (1944) the beneficial effect of ascorbic acid in two cases, she thought was mainly due to its action as a agent in prolonging the more absorbable form, but in a third it evoked no response to iron, our patients had received 300 mg of ascorbic without effect.

The introduction of a potent therapeutic was made it possible to study such cases in more detail. It may be a coincidence that all the patients in our series present the combination of refractory hypochromic anaemia and a fat absorption defect, because we have a large number of patients with steatorrhoea and anaemia, but two were found elsewhere and the fat balance test was merely a routine investigation. There is, however, certain features which justify further study to the possible relationship between the two conditions. As Thaysen (1932) was the first to show, the haematological pattern of the steatorrhoea syndrome shows variations between blood pictures that are predominantly either macrocytic or hypochromic. In our experience both blood pictures are usually associated with an increase in the mean cell diameter, a slightly reduced mean corpuscular haemoglobin concentration, and, very rarely, with microcytosis. Nevertheless many cases remain in the macrocytic stage, whereas a small group may persist as a severe hypochromic anaemia and be considered idiopathic. In men the rarity of this condition usually leads to full investigation, but in women the diagnosis is often made in spite of the presence of hydrochloric acid in the test meal and the absence of microcytosis.

In our series of over two hundred cases of steatorrhoea of varied aetiology there were thirteen patients in whom serial blood examinations over a considerable period showed a persistent hypochromic anaemia. One responded normally to ferrous sulphate by mouth (Heath 1933), six had a slow and irregular rise in the blood count (fig. 7), and the remaining six cases are those reported in detail here. Other workers (Thaysen 1932; Ben et al 1932) have also commented on the poor response of the hypochromic cases to oral iron therapy, and it is not surprising that cases completely refractory to oral treatment are found in steatorrhoea. The response to intravenous iron indicates that the defect of haemoglobin is normal, and the inference of an absorption defect is obvious. The frequent development or maintenance of macrocytosis after parenteral iron therapy is of particular interest, for it suggests that the blood picture in steatorrhoea is essentially macrocytic, the characteristic fluctuations due to iron deficiency. Nevertheless we feel that further studies are needed before an unequivocal opinion can be expressed on points.

SUMMARY

Criteria are given for the diagnosis of refractory hypochromic anaemia.

Six cases, with an associated fat absorption defect, responded to intravenous iron, with the production of macrocytosis in five cases.

It is suggested that a high proportion of patients with refractory iron deficient anaemia will be found to have steatorrhoea if fat balance tests are done.

This work is part of a general investigation of the steatorrhoea syndrome which is being carried out in the department of gastroenterology (Prof. I. L. Hardy), Medicine.

unott), and pharmacology (Prof A C Frazer) in the

BLANCING EFFECT OF CORTISONE ON TUBERCULOSIS IN THE MOUSE

P D'ARCY HART R J W REES

M.D Camb, F.R.C.P M.B, B.Sc Lond

rom the National Institute for Medical Research, London

ALTHOUGH circumstantial evidence suggests that
nutrition, certain endocrine disturbances, fatigue, and
er factors can increase the susceptibility of human
ags to tuberculosis, experiments on laboratory
mals have yielded few clear cut and reproducible
tances of such action

Vo nutrient or class of nutrient, or even a general reduc
a in caloric intake, has been incriminated conclusively
e infected intravenously or intracerebrally with tubercle
will lived a shorter time on certain natural diets than on
ers, but these effects have not yet been successfully
lysed (Dubos and Pierce 1948, Sengupta and Howie 1949)
changes in the form, incidence, or duration of tuberculous
ions in rats given protein-deficient diets, and infected
avenously, were observed by Metcalf et al (1949), and
experience of Glover and Hart (1946) with protein deficient
ts infected by an inhalation method was similar More
omising results have been obtained recently with dietary
ids Diets rich in egg yolk were reported by Curo and
osso (1947) to aggravate the course of experimental tuber
losis in guinea-pigs, and Hedgecock (1948) found that the
ortality was greater, and the lung disease more extensive,
t mice infected intravenously and given diets containing
nseed or olive oil or oleic acid, than in control mice on a lipid
ree diet Apart from suggestions that vitamin C deficiency
hances experimental tuberculosis in guinea-pigs (e.g.
reene et al 1936) the results of studies on the influence of
itamin deficiencies upon this infection in laboratory animals
ave been indefinite or contradictory (see Rich 1944)

Much of the work on the influence of hormones on suscep
bility to experimental tuberculosis has also given indefinite
r contradictory results, as, for example, with the oestrogens
nd the gonadotropins Lurie Abramson, and Allison (1949)
elieve that the hormone effects may be small, and that they
ere able to detect enhancement of the disease in rabbits by
nomic gonadotropin because they used highly inbred
animals of genetically uniform stock and closely similar
ereditary resistance to tuberculosis and infected them
intracutaneously The rôle of the thyroid in resistance is also
ncertain Reports suggest that susceptibility in guinea-pigs
s increased by thyroidectomy, though the effect appears to
be small (e.g. Izzo and Cicardo 1947) In spite of strong
vidence of a predisposition of human diabetics to tuberculosis,
we have been unable to demonstrate any change in suscepti
bility in mice given alloxan diabetes, followed by an acute
tuberculous infection.

Apart from the obvious possibility that as yet undis
covered factors are operative, a number of reasons could
be suggested to account for the meagre results in this
experimental field, for instance, it may be difficult to

gressive infection following intravenous inoculation in the
mouse or rat or subcutaneous inoculation in the guinea-pig
Such methods may be more suitable for detecting retard
ation of tuberculosis due to an increase in host resistance
than for detecting aggravation of the disease due to
enhanced susceptibility We thought that if a stable
chronic infection in the lungs could be produced experi
mentally, any breakdown in resistance would be
manifested by a flare up of the established lesions,
which might or might not be fatal, such a process
might throw light on exacerbations in human chronic
pulmonary tuberculosis The mouse was a suitable
species to use, because of its high natural resistance
to tuberculosis

We have recently produced in mice a chronic pulmo
nary tuberculous infection sufficiently stable to serve as
a test infection, and in view of its wide range of activity
on host defences, we examined 'Cortisone' for its ability
to break down the resistance in mice so infected We
have also, for comparison, tested the effect of the drug
on acute tuberculous infection in mice

Fig 1—(A) Gross specimen of lungs from a mouse with a stable chronic tuberculous infection ($\times 1\frac{1}{2}$). (B) Lungs from a similar mouse after a course of cortisone ($\times 1\frac{1}{2}$).

Fig 2—(A) Section through a lobe of the lung from a mouse with a stable chronic tuberculous infection, showing many small discrete lesions Hæmatoxylin and eosin ($\times 6\frac{1}{2}$). (B) The same type of infection after cortisone treatment showing massive partially coalescent necrotic lesions replacing most of the lung field Hæmatoxylin and eosin ($\times 6\frac{1}{2}$).

for gall stones in 1939, since then had recurrent attacks of upper epigastric pain with continuous vomiting lasting 2-3 days, suggestive of chronic pancreatitis. Bowels usually opened 2-3 times daily, but had frequent attacks of diarrhoea with bulky pale motions.

On admission she was pale but well nourished, height 5 ft 4½ in, weight 8 st 8 lb. Koilonychia present. Tongue normal.

Investigations—Fat absorption—85%. Normal gastric acidity and glucose tolerance. Blood proteins 6 g per 100 ml (albumin/globulin ratio normal). Van den Bergh reaction negative. Blood calcium normal. X ray films of chest and abdomen normal.

Response to Treatment—This patient's hypochromic anaemia had never responded to iron by mouth, and in view of our previous experience, a fat balance test was performed and she was found to have steatorrhoea, possibly due to chronic pancreatitis. Daily injections of intravenous iron to a total of 2 g relieved her malaise and nocturnal cramps and improved her energy, but her dyspnoea on exertion remains. Her blood counts have returned to normal, but, up to 2 months after the course of treatment, there has been no macrocytosis.

Fig. 7—Rate of regeneration of haemoglobin in response to iron by mouth: 1, normal (Heath 1933); 2-6, in steatorrhoea (2 is almost completely refractory, and 3-6 are partially refractory).

rates of regeneration were similar to those reported elsewhere (Goetsch et al 1946). The maximum rate of haemoglobin regeneration was 0.25 g daily, calculated at weekly intervals, and the minimum, seen in a patient who received injections twice weekly, was 0.04 g. In the three cases where the reticulocyte response could be followed the "peaks" were higher than with iron by mouth and in one the peak was 23%, compared with the expected value of 8% (Minot and Heath 1932).

These patients have been under observation for 6-18 months, and so far further iron has not been necessary. A striking feature of the results has been the rapid improvement in the mean corpuscular haemoglobin concentration and the pronounced increase in the mean cell volume, associated with obvious macrocytosis in the peripheral blood films, in five out of the six patients.

DISCUSSION

If radioactive iron is injected intravenously (Finch et al 1949), 75% will be incorporated into the erythrocytes within ten days, the remaining 25% being mainly stored. There seems to be a reciprocal relationship between the amount of intravenous iron utilised and the quantity stored, and it is the uncertainty of the state of the existing stores at any given time that prevents any accurate estimation of the amount needed by the

Fig. 6—Response in case 6.

body. It has been assumed that 25 mg of iron will produce a rise of haemoglobin of 1%; this assumption does not hold in pregnancy (Scott 1949). In this series the total amount of iron was up to twice that needed to bring the blood to normal.

There has been little work reported on the refractory hypochromic anaemia. Powell (1944) showed the beneficial effect of ascorbic acid in two cases; she thought was mainly due to its action as a agent in prolonging the more absorbable form, but in a third it evoked no response to iron. Our patients had received 300 mg of ascorbic acid without effect.

The introduction of a potent therapeutic agent made it possible to study such cases in more detail. It may be a coincidence that all the patients in our series present the combination of refractory hypochromic anaemia and a fat absorption defect, because with a large number of patients with steatorrhoea under care, but two were found elsewhere and the fat balance test was merely a routine investigation. There is, however, certain features which justify further attention to the possible relationship between the two conditions. As Thaysen (1932) was the first to show, the characteristic pattern of the steatorrhoea syndrome is variations between blood pictures that are predominantly either macrocytic or hypochromic. In our experience both blood pictures are usually associated with an increase in the mean cell diameter, a slightly reduced corpuscular haemoglobin concentration, and, very rarely, with microcytosis. Nevertheless many cases remain in the macrocytic stage, whereas a small group may persist as a severe hypochromic anaemia and be considered idiopathic. In men the rarity of this condition usually leads to full investigation, but in women the diagnosis is often made in spite of the presence of hydrochloric acid in the test meal and the absence of microcytosis.

In our series of over two hundred cases of steatorrhoea of varied aetiology there were thirteen patients in whom serial blood examinations over a considerable period showed a persistent hypochromic anaemia. One responded normally to ferrous sulphate by mouth (Heath 1933), six had a slow and irregular rise in the blood-count (fig. 7), and the remaining six cases are those reported in detail here. Other workers (Thaysen 1932, Brown et al 1932) have also commented on the poor response of the hypochromic cases to oral iron therapy, and it is not surprising that cases completely refractory to oral treatment are found in steatorrhoea. The response to intravenous iron indicates that the synthetic rate of haemoglobin is normal, and the inference of an absorption defect is obvious. The frequent development of macrocytosis after parenteral iron therapy is of particular interest, for it suggests that the blood picture in steatorrhoea is essentially macrocytic, the characteristic fluctuations due to iron deficiency. Nevertheless we feel that further studies are needed before an unequivocal opinion can be expressed on this point.

SUMMARY

Criteria are given for the diagnosis of refractory hypochromic anaemia.

Six cases, with an associated fat absorption defect, responded to intravenous iron, with the production of macrocytosis in five cases.

It is suggested that a high proportion of patients with refractory iron deficient anaemia will be found to have steatorrhoea if fat balance tests are done.

This work is part of a general investigation of the steatorrhoea syndrome which is being carried out in the department of gastro-enterology (Prof. F. L. Hardy), Medicine (

CT OF CORTISONE ON CHRONIC TUBERCULOSIS

Experiment 1—22 apparently healthy mice (average now 25 g), which had been infected 9 weeks with 0.0006 mg of H37RV, were randomised into groups of 11. One group was given cortisone daily until death or the 17th day of treatment, never came first, a maximum of 15 injections received, the other group served as a control. The experiment was terminated 22 days after the first day of treatment, and all surviving animals of both groups. The results are shown in table I. The control mice appeared apparently fit, gained weight, and none died, as the treated mice showed signs of sickness and eight from the 11th day onwards. 2 of them died on 13th day and 6 from the 19th to the 22nd days, a total of 8 out of 11 being dead at the termination of the experiment.

In addition to the differences in mortality, the two groups were distinguished by the pathological changes. The 11 controls had pink, air containing lungs with small, mottled grey lesions as previously described, whereas 8 of the 11 dead, and 1 out of 3 of the killed, cortisone treated mice had voluminous congested lungs containing many very large, raised yellow grey lesions (fig. 4b), the remaining 3 mice had lungs similar to those of the controls. No macroscopic extrapulmonary foci were seen in either group, but whereas the control animals all had splenomegaly (a characteristic feature of murine tuberculosis), the spleens of the treated mice were small.

The histology of the lungs in the controls has already been described (figs. 2A and 3A). The cortisone group were in striking contrast. Instead of cellular foci, the large lesions consisted of massive, partially coalescent areas almost entirely made up of necrotic tissue, and replacing most of the lung substance (figs. 2B and 3B). The cells at the periphery of these areas were mainly macrophages, and in no way differed from the cellular reaction seen in the lesions in the control lungs. The small amount of unaffected lung tissue was markedly reduced. In contrast to the few tubercle bacilli in the control lungs (fig. 4A), and their limitation to the cellular reaction areas, there were tremendous numbers of organisms in the necrotic areas, and some in the surrounding lung tissue, of the cortisone treated group (fig. 4B). Minute proliferative foci, containing scanty tubercle bacilli, were seen in some of the other organs, particularly the liver and kidneys, but the distribution and appearances were identical in the two groups of animals, however, extrapulmonary tubercle bacilli were present in most of the tissues examined from the treated mice but not from those in the controls. This difference is presumably due to a terminal overwhelming bacteraemia in the former.

Experiment 2—36 apparently healthy mice (average weight now 24 g), which had been infected 8 weeks previously with 0.0006 mg of H37RV, were randomised into three groups of 12. In addition, 10 uninfected mice, taken from stock at the time the others were infected (average weight now 25 g), were randomised into two groups of 5. One infected and one uninfected group were given cortisone 0.5 mg daily, and a second infected and the other uninfected group 0.25 mg daily, until they died or the experiment ended, the third infected group served as an untreated control. The experiment was terminated, and all survivors killed, 22 days after the first day of treatment in the groups receiving 0.5 mg, and in the untreated tuberculous controls, and after 29 days in those receiving 0.25 mg, the maximum numbers of injections received being 19 and 25 respectively.

The results are shown in table II. The tuberculous control mice and the uninfected controls on cortisone remained apparently healthy and none died, whereas both treated tuberculous groups showed signs of sickness

after a latent period, and some of the animals died, both sickness and deaths occurred some days later in those given the smaller than in those given the larger dose. Thus at the higher dose, 9 of the 12 mice died from the 10th day to the termination of the experiment and 5 of these 9, as well as 2 of the 3 killed, had the same gross pulmonary tuberculous lesions as in the first experiment. At the lower dose, after 1 unexplained death on the 9th day, 8 of the 12 mice died from the 19th to the termination, and 6 of these 8, and none of the 3 killed, had similar gross lesions. The remaining mice in the cortisone treated groups had chronic changes in the lungs similar to those in the tuberculous controls. There was, however, a complication in that 4 of those on the higher dose and 2 on the lower (i.e., 6 of the total 24 treated animals) had died with necrotic foci in the liver, apparently due to various non acid fast bacteria. Nevertheless, the contrast, both microscopic and macroscopic, between the lungs containing the gross tuberculous lesions and the chronic proliferative changes seen in the untreated controls was as striking as in the first experiment.

EFFECT OF CORTISONE ON ACUTE TUBERCULOSIS

Experiment 3—35 mice, weighing 18–20 g, were randomised into three groups. Two of the groups, containing 10 and 20 animals respectively, were infected with 0.06 mg of H37RV. The first of these was treated with cortisone 0.5 mg daily from the day of infection, and the second served as an untreated control, 10 being allowed to die naturally and 10 being killed at selected intervals (see below). The third group, containing 5 uninfected mice, also received cortisone 0.5 mg daily, and served as a toxicity control. Cortisone treatment was continued until death or the 10th day of treatment, whichever occurred first, a maximum of 9 injections being received.

The results are shown in table III. The untreated infected control mice were at first apparently fit and gained weight, but their condition gradually deteriorated and 9 of the 10 died between the 14th and 24th days after infection (the remaining animal having died on the 5th day from non specific causes). On the other hand, the treated infected mice began to lose weight in the first week, though they appeared otherwise healthy, on the 9th day after infection (10th day of treatment), however, their condition suddenly deteriorated (necessitating termination of treatment), and 4 died on the next day and all 10 were dead 15 days after infection. The toxicity control mice, although gaining weight more slowly than normal untreated mice, remained apparently fit and none died. Thus there was a striking difference in mortality between the treated and untreated infected mice.

At necropsy, the 9 untreated mice dying with tuberculosis showed obvious lung involvement, and 5 of them pericardial lesions. The cortisone treated infected group died with far less obvious, although more disseminated, disease (9 of the 10 with pericardial, 5 with renal, and 5 with splenic involvement). It is unsatisfactory to compare the small lesions in the treated animals, which died early, with the more obvious changes in the untreated animals, which died later. Necropsy of the additional 10 untreated infected controls (half on the 11th and half on the 15th day after infection), during the period when most of the treated group were dying, gave a more useful comparison, because the period of infection was similar in the two groups, these killed untreated mice had only minimal lesions, less than in the treated group, and mainly confined to the lungs instead of being disseminated.

The histological comparisons were more clear-cut than the macroscopic. In the cortisone treated group, all the foci were undergoing necrosis, irrespective of the size, the site, or the survival period, and all were teeming with

Fig 3A—Section of a typical proliferative pulmonary lesion with minimal necrosis in a mouse with a stable chronic tuberculous infection. Haematoxylin and eosin ($\times 250$)

MATERIALS AND METHODS

Mice—Females of the albino Parkes strain (an inbred strain maintained at the National Institute for Medical Research) 18–20 g initial weight, were used. They were housed 5 or 6 in a box fed once daily on a stock mash diet, and weighed fortnightly.

Bacterial suspensions—*Mycobacterium tuberculosis*, strain H37Rv was grown for 7 days in Tween 80 albumin medium. The culture was centrifuged, and the bacterial deposit resuspended in Tween albumin saline solution, about 0.3 mg dry weight per ml, measured routinely by opacity in a photoelectric absorptiometer (all doses are expressed here as dry weight), such suspensions contained about 10^8 – 10^9 viable organisms per ml. The bacillary suspension, diluted in Tween albumin saline to contain the required dose in 0.5 ml, was injected into the tail vein.

Cortisone treatment—Cortisone, as a microcrystal suspension of the acetate (Merck), was diluted in saline, and the required dose was injected, in a volume of 0.5 ml subcutaneously into the nape of the neck once daily (excluding Sundays). A preliminary toxicity test showed that mice weighing 18–20 g would tolerate 0.5 mg cortisone daily for 14 days. This dosage corresponds on a weight basis with that used in rats by Selve (1949).

PRODUCTION IN MICE OF A STABLE CHRONIC PULMONARY TUBERCULOSIS

Parkes mice infected intravenously with 0.3–0.63 mg of strain H37Rv, consistently develop progressive and fatal tuberculosis in 1–5 weeks, the period depending on the actual dose. Smaller doses produce a more chronic

disease. With 0.0006 mg the mice, in general, do not fit and gain weight normally and up to 3 weeks after infection none die. Less than 10% of the animals go sick and die between the 3rd and 6th weeks. In the 0.0006 mg group more susceptible mice, about half the lungs contain large necrotic lesions and the remainder smaller, more discrete, proliferative lesions.

From the 6th week onwards, and at least until the 12th week, the mortality is only about 20%. Mice killed between the 6th and 12th weeks have pink, air-containing lungs of normal size, speckled with grey lesions varying in number and size but always relatively small (figs 1 and 2A). The similarity of these lesions in groups of mice killed at varying times during this period indicates no change, or, at the most, slight progression. Microscopically the lesions are proliferative, with minimal necrosis (fig 3A). The cellular response is predominantly macrophage, many of the macrophages are large, with abundant indistinct vacuolated cytoplasm, characteristic of the chronic types of infection in the mouse. The cellular lesions, which are discrete and evenly distributed in otherwise normal air-containing lung, are never associated with perifocal fibrosis. Tubercle bacilli are seen occurring either singly or in small groups, and they are confined to the cellular foci (fig 4A).

Mice with this chronic tuberculous infection, relatively non-progressive over the test period (and therefore referred to as stable), were used in the main experiments (1 and 2), which were made between 6 and 12 weeks after infection.

Fig 4A—As fig 3A showing the scanty tubercle bacilli. Ziehl-Neelsen ($\times 1320$)

groups in two of the experiments reported here, few of the varied flora found, it is possible that the causes in the mouse a breakdown in host resistance to a wide range of micro organisms. It may be that Antopol (1950) reported necrotic foci in the lungs of a proportion of mice treated with large doses of cortisone, all of which yielded *Corynebacterium tuberculosis murum* on culture. It cannot be assumed that the disastrous effects of cortisone on the tuberculous mouse are necessarily related to the disease in man. Hypersensitivity is said to play a considerable part in human tuberculosis, and from the few treated cases of this disease reported (Hench et al 1950), the depression of skin sensitivity in the guinea pig seems to have its counterpart in a reduction in allergic phenomena in man. On the other hand, a reduction in resistance, such as was shown in mice, might occur at the same time as a reduction in hypersensitivity in human tuberculosis, and must be watched for. It must be emphasised, however, that the doses of cortisone employed in the study have been relatively high—namely, 8–12 (on a weight basis) that commonly used clinically. Our two techniques, the main method, using mice, and the established chronic infection (experiments 1 and 2), satisfactory results in the unequivocal macroscopic and microscopic appearances of the lungs of the animals given the cortisone treated groups, so great was the difference from the controls killed at the same time, in spite of the variation in the latter within a limited range, it is reasonable to attribute the effects to the cortisone. Even in experiment 2, where a proportion of the mice was associated with non specific liver infections, the results were still definite. In the acute infection test (experiment 3), the earliness of the deaths, with the subsequent diffuse small pulmonary foci, in the cortisone-treated group made it difficult to attribute the cause of death to an enhancement of the infection, and it was necessary to rely on histological rather than on naked eye appearances. Furthermore, it was necessary to kill the treated mice during the experiment in order to make adequate histological assessment of the effect of the cortisone. The additional test in which the cortisone treatment was begun at the same time as infection with a very small dose of tubercle bacilli, selected to give a chronic infection and a low mortality, was seriously complicated by non specific liver disease. Yet the animals dying with tuberculosis showed such gross dissemination compared with the controls (all of which were alive at the time) that this method is worth further investigation.

SUMMARY

- 1 Few clear cut or reproducible instances of factors increasing the susceptibility of animals to experimental tuberculosis emerge from the many investigations, though a number of reasons can be given for these failures, which suggest that the acutely infected experimental animal is generally used may be unsuitable. For this reason a more chronic stable type of infection was sought.
- 2 Intravenous injection of 0.0006 mg dry weight of human type tubercle bacilli in mice produced such an infection, relatively non progressive over 6–12 weeks, and characterised during this period by small discrete, predominantly proliferative, pulmonary lesions containing many tubercle bacilli.
- 3 Cortisone 0.25–0.5 mg, given daily subcutaneously 2–3 weeks during the stable period of this chronic pulmonary infection, markedly exacerbated it, with a resulting high mortality, the voluminous lungs contained large coalescing necrotic lesions with great numbers of tubercle bacilli.
- 4 The more acute type of tuberculous infection in the mouse, produced by intravenous injection of 0.06 mg

of bacilli, was also enhanced by cortisone 0.5 mg daily, given from the 1st until the 9th day of infection.

5 The chronic infection test has proved highly satisfactory as a method for demonstrating enhanced susceptibility to tuberculosis due to cortisone, the acute infection test was more difficult to interpret.

6 The effect of cortisone on murine tuberculosis is unlikely to be due to depression of allergy or of collagen formation.

7 Although human tuberculosis differs considerably from murine, and the present dosage of cortisone was relatively high, these findings should be kept in mind since tuberculosis in man may possibly be aggravated similarly.

We are indebted to the Medical Research Council's Committee on ACTH, Cortisone, and Related Substances for supplying the cortisone, to Dr Janet S F Niven for advice on histological technique, and to Dr A A Miles for criticising the manuscript.

TREATMENT OF FIBROSITIS WITH ADRENALINE, EPHEDRINE, AND BELLADONNA CREAMS

TREVOR H HOWELL

M.R.C.P.E.

PHYSICIAN, GERIATRIC UNIT, ST JOHN'S HOSPITAL, BATTERSEA
 CONSULTANT PHYSICIAN, BERMONDSEY MISSION HOSPITAL,
 LONDON

In elderly patients, the treatment of fibrositis is not an easy matter. As Buckley (1937) has said, "The disease though not mortal, may add seriously to the burden of advancing years." The claims of Moss (1949) for adrenaline cream were therefore noted with interest, and the effects of this and other preparations have been investigated at St John's Hospital, Battersea, and the Bermondsey Mission Hospital. At Battersea, 70 outpatients attending the rheumatic clinic and 20 inpatients of the geriatric unit were treated with injections of cream instead of their customary injections of procaine, but physiotherapy was continued as usual. At Bermondsey, 20 outpatients received the cream only, without any physiotherapy. Of the patients at Battersea, 36 had fibrositis complicating rheumatoid arthritis, 35 had fibrositis complicating osteoarthritis, and 19 seemed to have a pure primary fibrositis. The cases at Bermondsey included 3 with rheumatoid arthritis, 11 with osteoarthritis, and 6 with fibrositis alone.

ADRENALINE CREAM

It was found that the base in which the adrenaline was administered made a difference in its effects. The most satisfactory preparation was that made by Messrs Howard Lloyd Ltd, of Leicester. This was easy to rub in and usually acted within a few seconds, in a strength

tubercle bacilli. Bacilli were particularly profuse in the pulp of the spleen, although this organ was very small, owing to gross diminution in the number of pulp cells and smaller malpighian bodies as a result of the cortisone. In contrast, the untreated control mice, both those killed and those dying up to the 20th day, had proliferative lesions, with relatively few tubercle bacilli, even in the animals dying later, although the pulmonary lesions showed early necrotic changes and many bacilli, the extrapulmonary foci remained proliferative with scanty organisms. In all these control animals the spleens were enlarged, owing to a generalised cellular hypertrophy, as is typical of murine tuberculosis, they contained only isolated small groups of bacilli.

In another experiment the course of cortisone was started, as in experiment 3, on the day of infection, but the infecting dose was the small amount of tubercle bacilli (0.0006 mg) used to produce the benign chronic infection in experiments 1 and 2. Unfortunately, half the treated mice died with liver infections associated with various non acid fast bacteria. The experiment is worth mentioning, however, since the remainder died with tuberculosis between the 17th and 29th days after infection, and all of these had marked pulmonary lesions with gross dissemination in the heart and kidneys. These findings contrasted with those in the untreated mice, none of which had died during this period, and which, on the 29th day, had the usual limited pulmonary tuberculosis of chronic type and no extrapulmonary dissemination. The picture in the treated animals is characteristic of an acute infection from a much larger dose of tubercle bacilli.

DISCUSSION

Cortisone has shown a very powerful action on a stable chronic tuberculous infection in mice (experiments 1 and 2). After a latent period, lesions originally proliferative in character became enlarged and necrotic, the bacilli increased enormously in number, and most of the mice died. We have never observed this change in chronic tuberculous infection of this type in untreated mice. It resembles the change from a proliferative to a necrotic reaction that may be seen in an acute infection following a larger dose of bacilli. The flare up associated with cortisone treatment was confined to the lungs, the minute foci found in other organs differing in no way from those in the controls. When cortisone was given immediately after a comparatively large dose of tubercle bacilli, calculated to produce an acute and fatal infection (experiment 3), the treated animals died even earlier than the controls. Histologically, the lesions in the former were necrotic at a time when those in the latter showed only a proliferative reaction, the bacilli were more numerous and the visceral dissemination more conspicuous in the treated animals than in their controls. When

cortisone treatment was begun immediately same small infecting dose as was used to produce benign chronic infection, the survival period was shortened, and necropsy revealed gross dissemination of the disease, particularly in the heart and kidneys, as is found after an acute infection from a larger inoculum.

The raised mortality, the necrosis, and the very number of tubercle bacilli in the lesions, observed in the experiments, are consistent with a marked breakdown in resistance, and are presumably due to the cortisone.

In the first experiment 2 of the 11 mice died receiving the drug, but most of the deaths took place a few days after the end of the course. It is possible, therefore, that withdrawal of the drug was responsible. However, in experiment 2, in which cortisone at dose levels was continued until death or termination of the experiment, the mortality and pathological changes were similar to those in experiment 1, so that an explanation is unlikely.

Although the mechanism of these enhancing effects is obscure, certain factors can probably be excluded. Hypersensitivity cannot be demonstrated in the mouse by a tuberculin skin test, and the depression of tuberculin reaction by cortisone in the guinea pig (Miles 1950) is therefore not necessarily relevant. Nor is the retarding effect of cortisone on fibrous tissue formation in the tuberculous guinea pig (Karlson 1949) or on wound healing in the rabbit (Ragan et al. 1949) pertinent to chronic pulmonary tuberculosis in the mouse where no fibrous reaction is evident.

We have no clear explanation for the deaths associated with necrotic foci in the liver, seen in the cortisone-treated mice.

INTERPRETATION OF HISTAMINE AND NSULIN TESTS IN PATIENTS WITH PEPTIC ULCERATION

J N HUNT

M.B., Ph.D. Lond.

DR LECTURER IN PHYSIOLOGY, GUY'S HOSPITAL MEDICAL SCHOOL, LONDON

IENTS with peptic ulceration have abnormalities astric secretion in response to histamine and insulin e responses have been well described by Ihre (1938) he gastric secretory mechanism may be considered having three parts (1) receptors of stimuli which mately activate the gastric mucosa, (2) the connect as, either humoral or nervous, between the receptors a peripheral effectors, and (3) the peripheral effectors e, the gastric secretory cells When there is some normality of secretion, the fault may lie in any one, several, of these three parts

The subcutaneous injection of 0.1 mg of histamine d phosphate per 10 kg of body-weight usually pro es a copious flow of gastric juice in man The amine seems to act directly on the gastric mucosa te it is effective in animals after complete extrinsic erration of the stomach Here then is a method of ing one of the three parts of the secretory system in ation If the response of the gastric mucosa to al physiological stimuli is proportional to its response histamine, two persons who respond equally to hista e may be considered to have equal peripheral secretory ctivity, or, more generally, the peripheral secretory ctivity to normal stimuli is proportional to the onse to histamine

TABLE II—MEAN VOLUMES OF ACID COMPONENT SECRETED IN RESPONSE TO HISTAMINE AND INSULIN

—	Normal people	Patients with	
		Gastric ulcer	Duodenal ulcer
Number of persons	18	17	13
Histamine (H) (ml)	91.6	62.4	119.6
Standard error	± 7.1	± 13.1	± 13.1
Insulin (I) (ml)	118.7	102.7	145.8
Standard error	± 9.5	± 14.7	± 17.0
I/H	1.30	1.23	1.23
Standard error of I/H	± 0.14	± 0.26	± 0.19

The intravenous injection of 20 units of insulin usually produces a flow of gastric juice slightly greater than that stimulated by 0.1 mg of histamine acid phosphate per 10 kg of body weight The secretion is the result of hypoglycæmia since it is abolished when the blood-sugar level is prevented from falling by the injection of glucose The site of the receptors for this response to hypoglycæmia is not known, but the response is abolished by vagotomy Presumably, therefore, hypoglycæmia stimulates gastric secretion proximal to the effector mechanism Thus, if two persons differ in their responses to equal hypoglycæmic stimuli, the cause of the difference may lie in one, or any combination, of the three parts of the gastric secretory mechanism However, a method of assessing differences in the peripheral secretory organ with histamine has already been considered Thus, if two persons differ in their secretory responses to hypoglycæmia but not in their responses to histamine, the difference may be ascribed to the receptors and connector pathways More quantitatively, if the secretory response (I) to a standard hypoglycæmia is divided by the secretory response to a standard dose of histamine (H), I/H will be proportional to the total stimulus bearing on the gastric effectors—i.e., the reactivity to hypoglycæmia of the receptors and connectors

By combining the results of histamine and insulin tests in this way it is possible to assess tentatively the separate reactivities of the peripheral secretory organ and of the receptor connector mechanism

So far the gastric mucosa has been considered as a simple organ, which it is not, since it secretes acid, pepsin,

TABLE III—MEAN VOLUMES OF ALKALINE COMPONENT SECRETED IN RESPONSE TO HISTAMINE AND INSULIN

and mucus among other things There is ample evidence that the various parts of the secretory mechanism are separately controlled, since the composition of the gastric juice varies with the stimulus to secretion. Therefore separate secretory mechanisms for the individual components must be considered in terms of their receptor-connector units and their peripheral effectors

Hitherto the secretory response of the stomach has been measured in terms of the amounts of acid and pepsin produced Recently, however, the pioneer work of Hollander (1938) in dogs has been extended to man, and it has proved possible to estimate the concentrations of ions in two hypothetical components of human gastric juice which together account for the vast majority of the inorganic constituents of the gastric juice (Fisher and L 3

of 1 in 5000 The composition of this base was not divulged

Shortly after beginning to rub the cream into the "trigger point," or point of maximal tenderness, one could feel the skin soften This allowed irregularities in the muscle to be palpated. Sometimes—e.g., in the trapezius muscle—small rounded nodules could be felt, sometimes—e.g., on the outer aspect of the thigh or the inner side of the upper arm—corrugations were noted As deep massage proceeded, the nodules or corrugations became softer and smaller until in most cases they disappeared When the muscle had become soft and smooth, the patient found that the pain had gone Several patients had three or four nodules in different layers of muscle, with the result that effective treatment of one nodule merely uncovered another

The deeper the site of pain, and the fatter the patient, the harder it was to succeed with this form of therapy The 7 Battersea patients whose pain was not relieved by massage with adrenaline cream were all very fat women with tenderness deep in the thigh or groins The other 83 reported benefit and disappearance or diminution of pain lasting from ten minutes to five days, the average duration of relief being twelve hours Of the outpatients at Battersea, 12 were discharged as cured within two months of starting treatment The remainder of the patients at this hospital could be kept relatively free from pain with a combination of adrenaline cream every night and physiotherapy twice a week Of the 20 Bermondsey patients, 17 reported temporary relief lasting from four to sixteen hours each day, this enabled most of them to have a comfortable night's sleep if they applied the cream on going to bed

EPHEDRINE CREAM

The greatest defect of adrenaline cream was that its effect lasted so short a time, this led some patients to ask for injections of procaine instead of the ointment Ephedrine in a strength of 1 in 100 was therefore tried In the first place, experiments had to be made to find a suitable base for this cream Pure vanishing cream—e.g., stearic acid paste *BPO*—did not allow of deep massage, because it disappeared too quickly Cold creams required too much friction to ensure absorption, though adrenaline in a vanishing cream base was used at Bermondsey for a time The formula eventually chosen was

Emulsifying wax	20 parts
Wool fat	10 "
Chlorocresol	0.05 "
Water	100 "

A 1% ephedrine cream in this base was tried in 63 patients at Battersea and 15 at Bermondsey Except in 2 cases, the relief obtained lasted longer than with the adrenaline cream The shortest period of relief was eight hours and the longest eight days, and freedom from pain for twenty-four to forty-eight hours was not unusual When the ephedrine cream was massaged in by the physician, the patient began to notice relief of pain within 40 seconds and relief was complete by 90 seconds if the site of pain lay in superficial muscles, such as the long flexors of the fingers or the quadriceps femoris This was a little slower than the action of adrenaline cream in such places

BELLADONNA CREAM

On the hypothesis that adrenaline and ephedrine might relieve pain by acting through the autonomic nervous system, the effects of belladonna were tested Our cream base with 25% of the liquid extract of belladonna *B P* was applied in 16 cases at Battersea and 8 at Bermondsey This acted more slowly than ephedrine, taking 1 minute 10 seconds to relieve pain at the shortest

The duration of relief was much the same as with ephedrine, varying from an hour to eight days, half the cases obtaining two or three days' relief containing atropine 1 in 100 and hyoscine 1 in 100 tested in 6 patients. These gave muscular relief which lasted for only four hours

CONTROLS

This form of treatment was difficult to assess against previous routine treatments, including my procaine and physiotherapy, gave varying results Several patients claimed that the relief after use of procaine did not start for twenty-four hours then lasted three or four days and by the fifth original degree of pain had often returned admitted much less benefit, with only a few hours' relief When the creams were rubbed deeply in, whether by the physician, the masseuse, or the patient, the effects were felt within a few minutes and lasted several hours at least Some of this relief was attributed to the massage, so 20 patients at Battersea were treated with a blank cream containing no medicament

It was found that the physician or the masseuse could induce some muscular relaxation and relief of pain in patients with fibrositis even when using the blank cream The relief took longer to appear than when active creams were used, three minutes being the shortest time taken Pain returned in two or three hours to even save one in the series, this woman had no more relief for three weeks

When the blank cream was issued to outpatients for home treatment, an interesting sequence of events was observed In cases where there had been satisfactory results from ephedrine or adrenaline there was no relief during the first week In the second and third weeks the patients reported a gradual increase of pain stated that the ointment seemed to be losing its effect A return to the medicated cream always gave better results No patient with active fibrositis claimed relief after weeks of the blank cream, but the patient whose pain had been absent for three weeks had no return of pain when the blank cream was used

PHYSIOTHERAPY

The creams gave relief for about the same period as the patients at Bermondsey, who received no physiotherapy, as to those at Battersea, where heat and massage were routine On the other hand, only 5 of the Bermondsey patients showed steady improvement and one was fit to be discharged in the trial period, daily applications produced freedom from pain but not even temporary cures At Battersea temporary cures of complicating fibrositis were not unusual in patients with rheumatoid arthritis or osteoarthritis It was therefore, that physiotherapy was definitely beneficial in cases treated with medicated creams

COMPARISON OF CREAMS

In an attempt to compare the efficacy of the medicated creams and the blank cream the duration of the relief obtained in roughly comparable cases of fibrositis at the two hospitals are set out in the accompanying table

EFFECT OF MASSAGE WITH MEDICATED AND BLANK CREAMS IN COMPARABLE CASES OF CHRONIC FIBROSITIS				
Duration of relief	Adrenaline	Ephedrine	Belladonna	Control
None	5 (24%)	6 (14%)	4 (25%)	12 (100%)
Less than 4 hr	7 (33%)	12 (28%)	4 (25%)	3 (25%)
4-12 hr	5 (24%)	12 (28%)	3 (19%)	0
12-24 hr	4 (19%)	13 (30%)	5 (31%)	1 (8%)
More than 24 hr				
Total no. of cases	21	43	16	0

the alkaline and the acid components neutralise each other, the response of the acid secreting cells be estimated directly from the amount of acid in the gastric juice

Following points have been established

Insulin and insulin stimulate the production of the acid and alkaline components

Components probably have the same composition in patients with peptic ulcers as in normal people

Patients with gastric ulcers secrete significantly less acid than patients with duodenal ulcers. This difference can be explained by a difference in peripheral secretory reactivity, as assessed with histamine

Patients with gastric or duodenal ulcers secrete significantly more alkaline component than did normal people. Patients with duodenal ulcers this can be entirely explained by supernormal peripheral secretory reactivity as assessed with histamine but in the patients with gastric ulcers there was also a supernormal reactivity of the central secretory unit to hypoglycaemia

Patients with duodenal ulcers secrete significantly more pepsin than did the two other groups, this can be explained in terms of supernormal peripheral secretory reactivity, as assessed with histamine

Division of the gastric juice into two hypothetical components is open to criticism on the grounds that the results are separated from the observations by a considerable amount of arithmetic. It is therefore worth considering any evidence which bears on the supposition that two components do exist

A litre of pure acid component is believed to contain 1 m eq of hydrogen ion, and a litre of the alkaline component is believed to contain 45 m eq of bicarbonate, a litre of acid component requires $160 - 45 = 115$ m eq of alkaline component to neutralise it. By extending this calculation with the data of table 1 it may be calculated that neutral gastric juice ought to contain 1 m eq of Cl^- per litre. In fact very many of the samples of neutral gastric juice recovered by Ilbre (1938) in patients with pernicious anaemia or with gastritis contained such a concentration of chloride. Further, samples of neutral gastric juice recovered by Dr A. H. Ilbre, of St Mary's Hospital, also contained this concentration of chloride (personal communication).

The original two-component hypothesis was suggested by Hollander (1938) by the fact that, when the concentration of neutral chloride in samples of gastric juice of patients was plotted against the concentration of acid, the points fell on a straight line. The general applicability of this relationship to the gastric juice of man may be seen from the accompanying figure. Thus, though the hypothesis ought to remain continuously under review, it far it explains the facts which have come to light.

The advantage of applying the two-component hypothesis may be seen by comparing the results of this examination of Ilbre's data with a previous examination (Hunt 1949) made without applying the two-component hypothesis. In the previous examination it was impossible to detect the supernormal central reactivity of patients with gastric ulcers.

The interpretation of the relationship between the amounts of juice secreted in response to histamine and insulin is based on a number of untested assumptions, but it at least has the advantage of unifying the experimental data within one concept.

The evidence which suggests that duodenal ulcer and gastric ulcer are distinct diseases has recently been summarised by James and Pickering (1949). The present paper adds further points to their arguments.

The finding of a supernormal central reactivity in the secretory mechanism of the hypothetical alkaline component in patients with gastric ulcers is of particular interest since it may explain the observation made by James and Pickering (1949) that the acidity of the fasting gastric contents after normal meals fell very considerably during the later part of the night in most patients with

gastric ulcers but did not do so in normal people or in patients with duodenal ulcers. The concentration of chloride in neutral gastric contents obtained from a patient with a gastric ulcer was found to be 135 m eq per litre (personal communication), which fact together with other evidence suggests that neutralisation was not the result of extragastric contamination. Thus one might suppose that the relative preponderance of the alkaline component in the gastric juice of fasting patients with gastric ulcers during the night is in part the result of a supernormal central reactivity. There is in addition evidence suggesting that the central connection of the stomach influences the secretory response of the gastric mucosa to histamine, since the amount of acid secreted is reduced by two thirds after vagotomy in man (Oberhelman and Dragstedt 1948), hence peripheral overreactivity may well be the result of nervous influence.

The data which have been considered were not obtained under normal conditions. Thus it remains to be established that there is a relationship between the response to food and the response to histamine and insulin. From work proceeding in this laboratory it appears that this correlation between the secretion in response to histamine and test-meal is in fact fairly close (Hunt 1950). This would encourage the transposition of the results for histamine stimulation to normal secretory function.

At this point the more practically minded may well ask whether the new information given here does anything to explain the formation and persistence of peptic ulcers. At the risk of stretching the significance of a few figures beyond reason, it is possible to outline the following tentative hypothesis.

Patients with duodenal ulcers secrete more acid and pepsin than do normal people or patients with gastric ulcers in response to insulin and histamine, and possibly in response to normal stimuli. They have in addition more acid gastric contents after meals. Not only are the gastric contents more acid in patients with duodenal ulcer, but also the stomach tends to be emptied more quickly than normal, which may be an additional cause of injury to the duodenal mucosa. Their gastric mucosa can resist this potentially harmful stimulus, but the mucosa of the duodenum cannot. The first cause of the oversecretion perhaps lies in the peripheral gastric secretory mechanism but probably ultimately depends on tonic influence exerted through the vagus nerves.

Patients with gastric ulcers do not secrete more of the potentially harmful acid and pepsin than do normal people, nor are their gastric contents more acid than normal. This fact suggests that their lesion is the result of a special susceptibility of the gastric mucosa. Possibly the supernormal central reactivity which has been postulated for the secretion of the alkaline component of the gastric juice may be associated with the changed susceptibility of the gastric mucosa.

SUMMARY

The secretory responses of the stomach to histamine and insulin in normal people and in patients with peptic ulcers have been analysed after the secretions have been divided theoretically into two hypothetical components containing the inorganic ions, and pepsin.

The response to histamine has been used to assess the peripheral secretory reactivity of the gastric mucosa.

The supernormal secretion of acid and alkaline components and pepsin by patients with duodenal ulcers can be entirely explained by their increased peripheral secretory reactivity, as assessed with histamine.

The supernormal secretion of alkaline component by patients with gastric ulcers can be explained partly by an increased peripheral reactivity and partly by an overreactive central mechanism.

The relevance of these points to the problem of peptic ulceration is considered.

Hunt 1950) The suggested concentrations of ions in the two hypothetical components are shown in table I, which applies to juice not only from normal people but also from patients with gastric and duodenal ulcers. It will be seen that one component contains acid, while the other contains bicarbonate which can neutralise the acid. Thus the amount of acid recovered from the stomach in these tests is, by itself, no measure of the amount secreted, since various amounts of acid are neutralised by the bicarbonate-containing component.

The data of table I may be used to divide samples of gastric juice derived from normal people and from patients with peptic ulcers into their two hypothetical components so that a secretory response may be assessed in terms of the volumes of acid component and alkaline component formed. The method of calculation is as follows.

Let Cl be the amount of chloride in a sample of juice (m eq.)
 A be the amount of acid in the same sample of juice (m eq.)
 N be the volume of alkaline component (ml)
 P be the volume of acid component (ml)
 $Cl = \text{amount of chloride in acid component} + \text{amount of chloride in alkaline component} = \text{concentration of } Cl = \times \text{vol. of acid component} + \text{concentration of } Cl = \times \text{vol. of alkaline component}$
 $Cl = 0.170 P + 0.125 N$

Similarly,
 $A = \text{amount of acid in acid component} - \text{amount neutralised by bicarbonate of alkaline component}$
 $A = 0.160 P - 0.045 N$
 These two equations may be rewritten to read
 $P = 4.521 A + 1.828 Cl$
 $N = 5.788 Cl - 6.147 A$

By the use of these two equations Ihre's (1938) results for 18 normal males, 17 males with gastric ulcers, and

TABLE IV—MEAN AMOUNTS OF PEPSIN SECRETED IN RESPONSE TO HISTAMINE AND INSULIN

	Normal people	Patients with	
		Gastric ulcer	Duodenal ulcer
Number of persons	18	17	13
Histamine (H) (units)	3634	3432	5472
Standard error	± 379	± 408	± 540
Insulin (I) (units)	8157	8923	15 044
Standard error	± 941	± 956	± 1845
I/H	2.24	2.60	2.74
Standard error	± 0.35	± 0.41	± 0.42

13 males with duodenal ulcers have been expressed in terms of the volume of the hypothetical acid and alkaline components in each specimen recovered by Ihre during two 60 minute periods of stimulation with histamine and insulin (tables II and III).

RESULTS

Acid Component

Table II shows that the patients with ulcers did not differ very greatly from the normal people in the volumes of acid component secreted in response to histamine, although the patients with gastric ulcers secreted slightly less, and the patients with duodenal ulcers slightly more, than the normal people. The difference between the means for patients with gastric ulcers and those with duodenal ulcers is statistically significant.

The same is true of the volumes of acid component secreted by these groups of people in response to insulin.

The ratio I/H in table II can be taken as an expression of the reactivity of the receptors and central pathways after compensating for the differences in differing peripheral secretory reactivities. The volume of acid component secreted in response to insulin has been divided by the volume in response to histamine for the three groups. Although I/H varies a little from group to group, the differences are not significant. Thus no real difference in the behaviour of their central pathways controlling the secretion of acid has been revealed between the three groups.

Alkaline Component

Table III shows the volumes of the hypothetical alkaline component secreted in response to histamine and insulin

by the same groups of people. In response to the secretion of the patients with gastric ulcers was more, and of those with duodenal ulcers 100% than that of the normal people. These differences between the three groups are statistically significant. In response to insulin the same trend is apparent; the secretion of the patients with gastric ulcers approaches that of those with duodenal ulcers, the difference between the patients with gastric ulcers and those with duodenal ulcers, which is apparent with histamine, is not apparent when insulin is used as stimulus. This can be interpreted to mean that there is a central overreactivity of the stimulating mechanism for the alkaline secretion in the patients with gastric ulcers as compared with patients with duodenal ulcers and normal people. This is indicated numerically by I/H ratio of 1.44 ± 0.15 as compared with 1.10 ± 0.15 . A more sensitive method of examining this point is to calculate the I/H ratio for each individual and to compare the mean values for the group. This leads to the same conclusions as the previous method, namely that the I/H ratios for the alkaline secretion in patients with gastric ulcer and in normal subjects differ by an amount which would be expected to arise by chance once in a thousand times.

Pepsin

Table IV shows the amounts of pepsin secreted by the same people in response to histamine and insulin. Patients with duodenal ulcers differ from the other two groups in that they secreted much more pepsin in response to histamine and insulin, but reference to the ratio I/H shows that the difference could be the result of different peripheral secretory reactivity rather than different reactivity of the central pathways.

The interpretation of these figures for pepsin, however, is subject to a further qualification. Histamine is considered not to stimulate pepsin producing cells only to wash out the preformed pepsin from the tubules of the gastric glands. The interpretation given for the results of the estimations of pepsin therefore includes an additional assumption that the amount of preformed pepsin lying in the tubules may be used as a measure of the peripheral secretory reactivity of the pepsin secreting cells. The correlation which exists between any given person between the amounts of pepsin secreted in response to histamine, and in response to insulin, after a previous injection of histamine, is in accord with this assumption.

DISCUSSION

The gastric juice has been considered as divided into an acid component, an alkaline component, and

THE LANCET

LONDON SATURDAY, SEPT 23, 1950

No Tools

WE know now, because we have been shown,¹ that the chest clinic physician is able to combine short-term hospital treatment of the patient with long-term domiciliary care, early tuberculosis can often be successfully treated, and the spread of infection checked. But these results cannot be expected unless there is access to hospital beds, a properly equipped clinic, and enough staff. In our present situation widely recognised as an emergency—chest physicians anxious to tackle the job on these lines ought to be able to count at least on the necessary tools, funds, and opportunities.

The modern chest clinic is the immediate descendant of the old dispensary. Sir ROBERT PHILIP, in Edinburgh, at the end of the last century, first devised a dispensary and domiciliary service, conducted by tuberculosis officers, to supplement the work of the hospital, and voluntary dispensaries were soon set up elsewhere on the same pattern. In 1912 most of these, with the rest of the tuberculosis service, became the responsibility of the major local authorities. The activity with which local authorities interpreted this responsibility is an old story. Taken by and large, the result was to produce a few first-class, some mediocre, and many poor dispensaries. Some of these were so badly housed and meanly equipped that the tuberculosis officers in charge of them might be forgiven if they sank into despairing apathy. A few of them gave up hope of any particular achievement in such a stony field and concentrated on their own motion to the position of medical officers of health, leaving in time the post of tuberculosis officer came to be widely regarded as mainly a stepping stone to the senior office. In 1948 the dispensaries suffered their change of master, and were handed over to the National Health Service. At one stride they became chest clinics, and the tuberculosis officers, often with no more equipment or help than they had ever had, became chest physicians to their areas. Moreover the physicians were now required to serve two masters, giving eight-elevenths of their time to the regional hospital board for diagnosis and treatment, and three elevenths to the local health authority for prevention.

Some chest clinics have seized their new opportunities to widen their scope. The Willesden Chest Clinic, with the cooperation of the Central Middlesex Hospital, has demonstrated how much can be done by combined hospital and domiciliary care. Such successes depend in part, however, on the accommodation, equipment, and staff at the disposal of the physician, and on the help he gets from his local hospital. A few are very well served.

The Paddington and Kensington Chest Clinic is one of the most spacious and best equipped. Built by a

voluntary committee in the years before the late war, it is set in a courtyard planted with flowers, and the pleasant modern building, with its large windows and fresh paint, has an air of competence likely to restore the spirits of a patient coming to be investigated. He is welcomed in a light and airy admission room, and is radiographed within a few minutes of arrival. The physician has clinical control, and the right of admission, in two wards for the treatment of pulmonary tuberculosis in St Charles's Hospital, Ladbroke Grove. If the patient requires chemotherapy or collapse treatment, these can be carried out either in his home or at St Charles's Hospital. Really urgent cases can usually be admitted at once, and other patients wait only two or three weeks. (Unfortunately there are not enough beds to serve all the patients in the area requiring inpatient treatment, and many still have to wait their turn for admission to sanatorium.) When collapse refills are needed they can be given at the clinic in a large well-lighted room, fully equipped and reserved for the purpose. There are enough health visitors to follow the case at home, enough clerks to look after the records, and enough record-storage space. The staff do not seem harassed, and the atmosphere is friendly and hopeful.

But compare the Paddington clinic's opportunities with those of a clinic in another part of London. As a dispensary this clinic came under a metropolitan borough, and it is now one of two clinics in the biggest group of its particular region, serving a population of 450,000 people. It is in the day to day clinical charge of an unestablished assistant physician, graded as a junior hospital medical officer, who works under the guidance of the one consultant chest physician to the group.

During the war the old quarters housing the dispensary were bombed, and it was transferred into a requisitioned house nearby. This, too, was badly shaken by the bombing, and it is now a derelict place indeed, the whole top floor being out of commission and the rest of the building showing serious cracks in the fabric. No paint has been used on it since before the war, the name of the clinic is almost illegible, the gate is broken, the drive is weed grown, the rooms are dark and dingy. Nothing could be more dispiriting to the patient. He can only feel that both he and his disease are held in contempt by the authorities responsible for his care. When the war ended, the borough might have repaired and painted the house, but they did not trouble, knowing that it would in time go to the National Health Service. Since 1948 the clinic has belonged to the regional board and remains as it was, except for some further decay through the passage of time.

The derelict shell would be tolerable if the equipment was good, but this is one of the clinics described by a correspondent, on p. 413, as "unfit to undertake active treatment on any large scale." There is no X-ray plant, not even a screening apparatus. Requests to the regional board to have one installed are met with a refusal, though the Ministry of Health has plenty of X-ray equipment available for purchase. Faced with the need to economise, the board is evidently unwilling to launch into an expense it has so far been able to avoid. So X-ray examinations are made at a general hospital by appointment, and normally take up to a fortnight to come through. (By a curious anomaly of administration a patient who goes up without appointment, but with a letter from his family doctor, is radiographed on the same day.) Since there is no screening apparatus at the clinic, refills for artificial-pneumothorax patients cannot be undertaken there, but in fact it would in any case be inadvisable to undertake them in such cramped, dirty, dangerous surroundings. Refills are therefore done at one of the teaching hospitals.

¹ Ball K. P., Jowles H., Toussaint C. H. C., Heady J. A. *Lancet* July 22 1950 p. 121.

orns in which the conception rate rose from 70% when a high calcium/phosphorus ratio in feeding stuffs was corrected.² Though some critics, such as GOULD,³ do not believe that grazing cattle on modern leys has any connection with fertility, a note of caution is certainly not out of place, and further research on the possible effects of leys grazing on the endocrine and reproductive systems of ruminants needs to be done before it can be concluded that the new leys are an unmixed blessing. An outstanding case of reproductive failure in grazing animals following the introduction of improved methods of pasture management was produced by the sheep of Western Australia which failed to breed normally when they were put on pastures rich in subterranean clover.⁴ The cause is believed to be an oestrogen in the clover, and it is noteworthy that significant quantities of oestrogen have since been detected in British pastures. In Western Australia it was found that beef cows thrived and reproduced normally on the pastures so inimical to the breeding of sheep, but this does not exclude the possibility that the revolution in British pasture practice which is now taking place may not in the long run affect the breeding capabilities of our stock. At least this is a risk that should not be absent from the thoughts of those responsible for our animal research programmes.

Recent findings on the relation between endocrine and nutritional factors also raise other possibilities that deserve attention. The work of BISKIND⁵ indicates that vitamin B deficiencies, by lowering the liver's capacity to inactivate endogenous oestrogens, may induce supernormal body levels of oestrogen, such as in women may lead to menstrual disturbances incompatible with normal reproductive function. Other dietary abnormalities, such as lack of lipotropic factors or ingestion of toxic substances which interfere with liver function, may have similar effects. Moreover, the work of HERTZ⁶ has shown that a sufficiency of certain vitamins such as folic acid is essential for normal growth and other responses of accessory sexual organs to the action of oestrogen. These examples emphasise the interplay of nutritional and endocrine factors in reproductive function, and suggest that, on further investigation, the problems of infertility in cattle may prove inconveniently complex.

Hæmatology

HEMATOLOGY, which many people still regard as a subdivision of clinical pathology, has now developed into a subject of sufficient scope for important international congresses. Gone are the days when it was mainly concerned with minutiae in the morphology of blood cells and the technique of cell counting—when it was the province solely of the microscopist. At the delegates at Cambridge comprised physicians, physiologists, and pathologists, and it was notable that, whereas the clinical pathologists were perhaps the smallest numerous group, academic pathology was very prominently represented. This illustrates the fact that

hæmatology has outstripped the information to be got from the histological section and considerations of morbid anatomy. Moreover the old battles about nomenclature seem to have died away. The recent proposal of an American clarification committee to adopt a new nomenclature for erythroblasts has met with little favour, judging by papers given at the congress; it seems to have been quietly dropped, for only one speaker used the proposed new names. The expected battle over the nomenclature of the Rh subgroups also seems to have been averted, apart from Dr WIENER himself, hardly any speaker used the Rh Hr terminology, the majority having adopted R. A. FISHER's CDE nomenclature.

Hæmatologists today must still use the morphology of blood and bone marrow cells as one of the pillars of diagnosis, but the limits of permissible variation are set far more widely than twenty years ago. New methods are being applied, and several workers showed electron microscope photographs of blood cells, but so far these are of purely academic interest, since no one knows just how artificial the pictures are. The main interest in hæmatology, as in some other branches of medicine, is now directed to the "pathological physiology," to sorting out the why and how of the disordered function in disease, and to utilising the information so gained for the refinement of diagnosis and treatment. As our report shows, the great majority of papers given at the congress dealt with these matters. The physiologists have taken up the subject of coagulation of the blood, and, though the number of "factors" discovered has produced some fog, we already have a much clearer idea of the ætiology of many disorders of blood coagulation and of what is and what is not practicable in therapeutics. The discovery of folic acid and of vitamin B₁₂ has reopened the whole question of the nature of the anti-pernicious-anæmia factor and how it works. Here biochemists, physicians, and pathologists cooperate in the research. The biochemists, even though they have a preliminary indicator in the growth of suitable lactobacilli, cannot be certain of the clinical activity of the fractions they have prepared until they are actually tried on a patient with pernicious anæmia in suitable relapse, this in turn depends on the careful correlation of the bone marrow changes with response to materials of known activity. A new development evident at the congress is the increasing use of histochemical methods on blood and bone marrow cells, either directly or on cells artificially maintained by tissue culture techniques. The minute biochemical changes caused by such substances as folic acid antagonists can now be followed in astonishing detail. The properties of heavy and radioactive isotopes are being applied to the problems of hæmatology, and many problems of metabolism have thus been solved by methods more precise than the round-about techniques needed before, for example, the congress heard striking accounts of the work done on the metabolism of iron and hæmoglobin. The study of blood groups has reached a high degree of complexity, and there is now enough information to enable the statisticians to add their contribution and so baffle the purely medical man. But, despite the genetics and the streamlined techniques for distinguishing one factor from another, immunohæma-

The chest physician has no beds in the area into which he can admit patients. When a new case comes to him all he can do is to fill in a form. A man has to wait an average of five months for a bed, a woman over a year. Because he cannot admit them for a few days to hospital, any domiciliary treatment he can give must be on the simplest lines. He can order bed rest, he can and does give *p* aminosalicylic acid, in suitable cases he can use streptomycin, and if all goes well he can keep them fit for collapse therapy later. He has not enough staff to undertake any further domiciliary treatment. Besides himself and his assistant physician, he has three health visitors and an almoner working at the clinic, but there is a population of over 150,000 to be served, and there are 13,019 people on the clinic register. Each of the health visitors has more than 450 on her visiting-list. What does such wholesale neglect of the tuberculosis load mean in terms of spread of infection? Moreover, there are only 28 tuberculosis beds—all for men—in the entire borough, and these have to receive cases from all over the region. There are no beds for women at all. Though the men's beds are under the care of the clinic chest physician, he is not allowed to admit patients to them, and they are mainly filled with chronic dying cases, all with positive sputum, for whom no other refuge has been found. Some of these are careless and untrainable in their habits. The nurses—mostly young Irish girls—dread (reasonably enough) having to nurse them, and some have been reported to suck their arms after a Mantoux test rather than risk a positive result. These patients need hostel care in the charge of well seasoned older nurses. We shall never be able to get the early cases nursed in an atmosphere of hope and enthusiasm if we expose young girls to this kind of risk: it can only increase the prejudice against tuberculosis nursing.

And this, unhappily, is no isolated example. The physician in charge is only one of a body of keen and capable men, up and down the country, who are not able to do the work for which they were appointed, because they lack the barest tools of their trade. The use of BCG is now to be added to their already impossible load, and how can the experiment be made with the necessary detail and thoroughness in such circumstances? The clinics cannot finish—or even begin—the job without the essential tools: rooms, X-ray plant, staff, and access to beds. To some extent, no doubt, the Minister's request to the general hospitals will improve matters: many are likely to fall in with it, and to release at least a few beds to the chest physician to use for his own purposes. But this measure requires to be supplemented by a more general respect for the needs of the tuberculous. Some years ago Dr BRIAN THOMPSON,² in a study of 406 cases, found that of any 8 patients with positive sputum, only 2 could be expected to survive five years, and only 1 ten years. His results indicate, in other words, that sputum positive tuberculosis has a considerably worse prognosis than many forms of cancer. Many of the people so threatened can be saved, as Willesden is showing by an effective clinic service, yet at present the effort necessary to save them is not being made.

Infertility in Cattle

NOBODY knows just how much milk and meat is lost to this country each year through infertility in cattle, but all agree that the loss is very large indeed. The term "infertility" here covers everything from outright sterility down to mere delay in getting cows or heifers into calf. Sometimes (usually in winter) this delay is due to periods of anoestrus, but some animals repeatedly fail to become pregnant even when the oestrous cycle is more or less normal, and it is these more subtle forms of infertility that are most baffling to the research worker and the practising veterinarian. The serious economic problem facing our dairy industry makes it necessary first to ascertain the extent of the trouble and then to find ways of overcoming it. The establishment of a network of artificial insemination centres, at which breeding records are kept, should soon provide statistics that will clearly reveal any fluctuations in breeding efficiency among dairy cows: indeed an analysis of existing records has already displayed variations in fertility, observed at two centres, for which no cause was found.¹ It is satisfactory to learn that the artificial insemination authorities are also making a survey of fertility levels in herds using natural service.

It is often said that the cows producing most milk are most prone to reproductive difficulties, from which the conclusion is drawn that breeding for high milk production is responsible for the apparent decline in fertility in recent years. Though there seem to be no figures proving that this contention is in fact correct, it should not be forgotten that both lactatory and reproductive functions owe allegiance to the pituitary gland, and it is quite conceivable that breeding for high milk production results in the selection of a pituitary which secretes less of the gonadotropins controlling reproduction and more of the prolactin and other hormones (such as somatotropin and perhaps ACTH) important for lactation. In many species lactation is associated with a quiescent state of the ovaries—the so called lactation anoestrus. Though the physiology of this phenomenon has never been fully worked out, it seems likely that, if a high output of prolactin is one of many necessary or limiting conditions for a high milk yield, the antagonistic action of prolactin may in some way be involved. Further work on these endocrine mechanisms might well increase our understanding of the relation between high milk production and fertility.

Another school of thought has sought to correlate reduced fertility in cattle with nutritional factors. Thanks to the efforts of STAPLEDON and his followers, the modern tendency in this country is all towards pasture improvement, and if it is true that our best producing animals are more prone to "physiological" reproductive difficulties than their less well bred sisters, we must bear in mind that it is precisely these bovine aristocrats that are generally the best fed and most likely to have access to modern lush leys. It has been suggested that a diet with excess of calcium in relation to phosphorus—which could arise from excessive application of lime—may interfere with breeding efficiency, and at the conference of the National Veterinary Medical Association held at Cardiff this month Mr S. L. HICNETT referred to a herd of

shorthorns in which the conception rate rose from 30% to 70% when a high calcium/phosphorus ratio in the feeding stuffs was corrected.² Though some authorities, such as GOULD,³ do not believe that feeding cattle on modern leys has any connection with infertility, a note of caution is certainly not out of place, and further research on the possible effects of modern grazing on the endocrine and reproductive systems of ruminants needs to be done before it can safely be concluded that the new leys are an unmixed blessing. An outstanding case of reproductive failure in grazing animals following the introduction of improved methods of pasture management was provided by the sheep of Western Australia which ceased to breed normally when they were put on pastures rich in subterranean clover.⁴ The cause proved to be an oestrogen in the clover, and it is noteworthy that significant quantities of oestrogen have since been detected in British pastures. In Western Australia it was found that beef cows thrive and reproduced normally on the pastures so inimical to the breeding of sheep, but this does not exclude the possibility that the revolution in British pasture practice which is now taking place may not in the long run affect the breeding capabilities of our stock. At least this is a risk that should not be absent from the thoughts of those responsible for our animal research programmes.

Recent findings on the relation between endocrine and nutritional factors also raise other possibilities that deserve attention. The work of BISKIND⁵ indicates that vitamin B deficiencies, by lowering the liver's capacity to inactivate endogenous oestrogens, may induce supernormal body levels of oestrogen, which in women may lead to menstrual disturbances incompatible with normal reproductive function. Other dietary abnormalities, such as lack of lipotropic factors or ingestion of toxic substances which interfere with liver function, may have similar effects. Moreover, the work of HERTZ⁶ has shown that a sufficiency of certain vitamins such as folic acid is essential for normal growth and other responses of accessory sexual organs to the action of oestrogen. These examples emphasise the interplay of nutritional and endocrine factors in reproductive function, and suggest that, on further investigation, the problems of infertility in cattle may prove inconveniently complex.

Hæmatology

HEMATOLOGY, which many people still regard as a subdivision of clinical pathology, has now developed into a subject of sufficient scope for important international congresses. Gone are the days when it was mainly concerned with minutiae in the morphology of blood-cells and the technique of cell-counting—when it was the province solely of the microscopist. The delegates at Cambridge comprised physicians, physiologists, and pathologists, and it was notable that, whereas the clinical pathologists were perhaps the most numerous group, academic pathology was very scantily represented. This illustrates the fact that

hæmatology has outstripped the information to be got from the histological section and considerations of morbid anatomy. Moreover the old battles about nomenclature seem to have died away. The recent proposal of an American clarification committee to adopt a new nomenclature for erythroblasts has met with little favour, judging by papers given at the congress it seems to have been quietly dropped, for only one speaker used the proposed new names. The expected battle over the nomenclature of the Rh subgroups also seems to have been averted, apart from Dr WIENER himself, hardly any speaker used the Rh/Hr terminology, the majority having adopted R. A. FISHER's CDE nomenclature.

Hæmatologists today must still use the morphology of blood and bone marrow cells as one of the pillars of diagnosis, but the limits of permissible variation are set far more widely than twenty years ago. New methods are being applied, and several workers showed electron microscope photographs of blood cells, but so far these are of purely academic interest, since no-one knows just how artificial the pictures are. The main interest in hæmatology, as in some other branches of medicine, is now directed to the "pathological physiology," to sorting out the why and how of the disordered function in disease, and to utilising the information so gained for the refinement of diagnosis and treatment. As our report shows, the great majority of papers given at the congress dealt with these matters. The physiologists have taken up the subject of coagulation of the blood, and, though the number of "factors" discovered has produced some fog, we already have a much clearer idea of the aetiology of many disorders of blood coagulation and of what is and what is not practicable in therapeutics. The discovery of folic acid and of vitamin B₁₂ has reopened the whole question of the nature of the anti-pernicious anæmia factor and how it works. Here biochemists, physicians, and pathologists co-operate in the research. The biochemists, even though they have a preliminary indicator in the growth of suitable lactobacilli, cannot be certain of the clinical activity of the fractions they have prepared until they are actually tried on a patient with pernicious anæmia in suitable relapse, this in turn depends on the careful correlation of the bone marrow changes with response to materials of known activity. A new development evident at the congress is the increasing use of histochemical methods on blood and bone marrow cells, either directly or on cells artificially maintained by tissue culture techniques. The minute biochemical changes caused by such substances as folic acid antagonists can now be followed in astonishing detail. tology (as it is called) has an oddly old-fashioned air. Just as the hæmatologists of two generations ago delighted to describe, say, a new cell with black granules instead of red, so the blood group experts report every serum they come across that will not fit those already docketed, and give it an imposing name bearing no relation to its relative importance, and there is no indication of when, or why, this collection should cease. Much hæmatology, of course, lacks a really scientific basis, witness the discussions on hypersplenism and hæmolytic anæmias, but efforts are constantly being made to find out the details of disordered function that will give that basis. Naturally new treatments were discussed at some length, but the shocks experienced over folic acid have induced a welcome scepticism and a desire for long-term studies that has extended to the latest panacea, adrenocorticotrophic hormone.

The proceedings at the congress should convince anyone that the study of advanced hæmatology is no longer a spare-time amusement for medical men primarily occupied in other fields. If hæmatology is to be advanced on desirable lines, then the physician, pathologist, or physiologist who takes it up must make it his main interest. To learn enough hæmatology for the routine run of clinical consultation, pathological diagnosis, or physiological teaching is not difficult, but if patients are to be given the best of diagnosis and treatment, and if research into the pathology and physiology of blood disorders in all their complexity is to be furthered, a higher degree of specialisation will be required. Today hæmatology can fairly claim any advantages obtainable from full specialist status.

Annotations

DOUBTS ABOUT THE TREATMENT OF POLIOMYELITIS

Stimson¹ draws attention to many uncertainties over the best methods of treating acute poliomyelitis. He considers the possible dangers of transporting patients long distances for admission to hospital, and refers to some observations suggesting that long journeys in the early stages of the illness induce more severe paralysis. He points out that it is also uncertain (1) whether lumbar puncture should be carried out in all cases, (2) whether the patient should be hydrated or dehydrated, (3) what is the proper use of sedatives, (4) whether muscle relaxing drugs should be administered, (5) what is the right treatment for urinary retention, and (6) what is the proper use of postural drainage and tracheotomy.

Certainly it is not always easy to get scientific guidance on what should be done. It is now widely held² that complete rest and muscular relaxation in the preparalytic stage increases the resistance of the spinal cord cells, and we must therefore bear in mind the possible harm done by long anxious consultations, exhausting physical examinations, lumbar punctures, and removal to hospital. It is essential, of course, to exclude meningitis, for this requires immediate specific treatment, but once this has been excluded, perhaps the less done in the preparalytic stage the better, apart from ensuring that the patient gets plenty of sleep. As regards treatment in the chronic stage of the disease, too, there are many different opinions, and reliable observations on the value of various methods of physiotherapy are strikingly few. In short, the

present position leaves much to be desired, and there is need for a special effort by research workers who have a good knowledge of the physiology of spinal cord, nerve cell, and muscle. Bourdillon et al.³ have been applying modern physiological knowledge to the study of cases treated in mechanical respirators, and thus is a useful step in the right direction.

THE LIQUORICE STORY

THE folk lore of medicine yields ample evidence of man's credulity as well as his enterprise. Extravagant claims have been confidently made for an infinite variety of plants, only a minute proportion of which survive in our pharmacopœias. But, like the fish in the sea, there may still be as good drugs in the vegetable kingdom as ever came out of it, and the pharmacologist must remain on the alert for discoveries in strange places.

In ancient China, and to the Greeks and Romans, liquorice "was almost an elixir of life"⁴, but the therapeutic virtues of glycyrrhiza have since been rated more modestly, and during the present century—in belated recognition of the pharmacological insight of etymologists—the sweet root has been taken at face value and has performed only the lowly if useful office of a flavouring believed to be inert. In our present issue, however, Professor Borst and his colleagues at Amsterdam relate how clinical observations on the supposed value of liquorice in the treatment of peptic ulcer raised a suspicion that it contains a potent substance. In many people, it seems, it produces an œdema which is not allergic in origin, and the wonderfully patient observations now recorded show that in normal subjects the Dutch liquorice extract taken by mouth has effects qualitatively identical with those of injected deoxycortone. Whatever may be the exact mechanism of its action, this evidently depends on the presence of normally functioning adrenal glands, which means that liquorice extract cannot be used as a substitute for deoxycortone in Addison's disease. Moreover, despite similarities in the biochemical pictures produced by adrenocorticotrophic hormone (A.C.T.H.) and liquorice extract, the latter is ineffective in rheumatoid arthritis.

This fascinating investigation in Holland provides an interesting point of contact between those who work on plant hormones and the researchers in animal endocrinology. Though the demonstration of a new deoxycortone-like substance does not in itself carry us much further in the therapeutics of adrenal deficiency, the discovery of a vegetable extract which reproduces the actions of a steroid hormone offers opportunities that will not be ignored by the pharmaceutical industry. A finding of minor but practical importance is that where water retention is particularly dangerous—e.g., in incipient heart failure—liquorice is a drug to be avoided.

THE NAMES OF VIRUSES

FOR some years students of plant pathology have been concerned to devise an orderly system of naming viruses, whether on the Linnean binomial, the numerical, or some other system. "Animal virologists," on the other hand, have felt no such urge, holding that in the present state of knowledge a codified system of naming is neither desirable nor practicable. In 1939 F. Holmes published a comprehensive binomial system dealing with plant viruses, and in 1948, in the last edition of Bergey's *Manual of Determinative Bacteriology*, he extended this to cover all viruses, including even phages. The rabies virus was to be called *Formido inexorabilis* Holmes, the common cold virus *Tarpeia premens* Holmes, and so on. Quite apart from the desirability of suddenly introducing a system covering all viruses, Holmes's attempt in

¹ Stimson P. H. *J. Pediat.* 1950 36, 704.
² Russell W. R. *Brit. med. J.* 1949 1, 465. Horstman D. M. *J. Amer. med. Ass.* 1950 142, 230.

³ Bourdillon R. B., Davies Jones E., Stott F. D., Taylor L. M. *Brit. med. J.* Sept 2 1950 p. 539.
⁴ Schofield M. *Pharm. J.* July 29 1950 p. 76.

the animal virus field was conspicuously unsuccessful, many unrelated viruses being lumped together and closely related ones placed far apart. A generally acceptable system could perhaps hardly be hoped for when a plant virologist, however well meaning, straved into a field strange to him. The fundamental weakness of the system, both as regards plant and animal viruses, was its emphasis on symptomatology as a basis for classification, with relative neglect of intrinsic properties of viruses.

Most British workers have felt that so unsatisfactory a system could safely be allowed to die a natural death. There is, however, a danger in such a course. Though experienced workers on animal viruses, almost to a man, reject the system, some may feel that its inclusion in Bergey's *Manual* gives it authority. In fact, writers in some American journals have begun to use these names, and it seemed possible that the pitch would be queued before the classification and naming of animal viruses was undertaken with due deliberation by those best qualified for the difficult task. We therefore welcome heartily the initiative of the International Congress of Microbiology, which met during August at Rio de Janeiro. This body resolved, first, that no decision should be taken at present to determine the valid starting date for virus nomenclature, and secondly that, pending acquisition of further knowledge, the use of a comprehensive system of scientific virus nomenclature was unwise. At the same time the congress took steps, through a subcommittee of its international nomenclature committee, to promote serious study of the nomenclature and classification of viruses. The effect of all this should be, on the one hand, to encourage orderly consideration of these subjects, and on the other, to make it clear that premature attempts to classify and name all viruses in advance of adequate knowledge are likely to hinder progress rather than help it.

FINANCING THE SERVICE

THE present hospital accommodation for mental patients is far short of what is needed. A memorandum on hospital estimates (R.H.B. [50] 80), issued by the Ministry of Health, tells us that, apart from the present overcrowding to the extent of 14%, insufficient provision is being made for greater demand resulting from the increase in the population and from any increase in mental illness. But boards and committees are again enjoined, in framing estimates for 1951-52, not to provide "for any developments which are not essential and urgent those which are merely desirable improvements must be deferred." Approval of management committees' estimates, which was delegated to regional boards only six months ago,¹ becomes again the prerogative of the Minister, who has lately called also for a running check on expenditure (R.H.B. [50] 41).

Hospital expenditure has lately been examined by the Committee of Public Accounts,² which observes that "if a suitable system of costing can be devised without excessive elaboration or staff cost, this should be a useful contribution to the economical administration of the hospitals." As to remuneration of professional people in the service, some of the assumptions which underlay the determination of payment have been proved false.

"It was assumed that there would be an increase in doctors' expenses of 55% over the 1939 figures. dentists' expenses were taken without any independent evidence as 32% of gross earnings. It was estimated that dentists could not work more than 1500 chairside hours a year involving about 1900 hours total work, without detriment to their efficiency. It was thought that the number of prescriptions dispensed by chemists would increase from 70 million a year under the old insurance scheme to

140 million under the Health Service, and it was expected that private sales of drugs and appliances and private ophthalmic practice would be reduced."

The Ministry of Health now thinks that dentists can work considerably more than 1500 chairside hours a year without loss of efficiency. "Dentists' earnings have been generally in excess of the Spens ranges, they have been considerably higher than those of doctors and the Ministry think it would be a serious state of affairs if this continued." Cuts in remuneration have been imposed, and the Ministry is now obtaining further information on earnings and expenses. With regard to doctors, "the Departments are not yet able to form precise conclusions," but "the available evidence suggests that the earnings of the general practitioners as a whole may have somewhat exceeded the Spens ranges"—assuming of course that (in the light of other professional incomes) an addition of 20% compensates adequately for the change in the value of money since 1939. The number of prescriptions dispensed by chemists in 1949-50 was about 200 million instead of the expected 140 million. Their remuneration has been reduced, but the Departments do not know the total payments made to individual chemists. The Departments were also unable to provide information about the total earnings of individual opticians.

"THE EXTINCT APE-MEN" MORE DISCOVERIES

AMONG the demonstrations which attracted particular attention at the International Anatomical Congress at Oxford was a series of photographs, exhibited by Dr R. Broom, F.R.S., and Mr J. T. Robinson, illustrating some of their recent discoveries of Australopithecine remains at Sterkfontein and Swartkrans. It is no exaggeration to say that these new finds are spectacular, for in several respects they are far more complete and perfectly preserved than any of the numerous remains of the Australopithecine already known. Natural size photographs of two fine lower jaws from Swartkrans (two out of the several mandibular specimens which have so far been recovered from this site) demonstrated the massive character of the mandible and its close resemblance in shape and general proportions to that of early types of man. They showed every tooth in position and in a perfect state of preservation. The morphological details of the dentition are those which are now known to be a consistent feature of the South African "ape men" (as indicated by at least seventeen specimens of upper and lower jaws)—that is to say, parabolic contour of the dental arcade, large molars and premolars, anterior premolars of the non sectorial human type, exceedingly small canines showing the earliest stages of attrition with flat wear at the tip, small incisors, and no diastema. Another photograph showed an Australopithecine os innominatum recently discovered at Swartkrans—the third pelvic bone of these extinct creatures to be found. Like the first specimen (discovered by Dr Broom in 1947 at Sterkfontein) it was found in situ, in direct association with jaws and teeth. It shows the same fundamentally human shape and proportions (very different indeed from that of anthropoid apes), but at the same time reproduces certain of the distinctive features already noted in the other specimens, whereby it makes an interesting contrast with *Homo sapiens*. But perhaps the most striking photographs on exhibition were those of two large Australopithecine skulls found by Dr Broom and Mr Robinson at Swartkrans only a few weeks previously, a brief reference to which appeared in the *Times* on July 26. In one of them, as Dr Broom has already reported, there is a small sagittal crest such as is usually developed in male gorillas (and sometimes orangs). This is clearly due to the development of powerful temporal muscles associated with the massive jaws, but in these two specimens the photographs made

¹ See *Lancet* 1950 1 403 426

² Fourth Report from the Committee of Public Accounts. Session 1950. H.M. Stationery Office. Pp. 27, 9d.

it clear that the skull as a whole (as well as the dentition, which includes as usual a remarkably small canine) shows many differences from that of a gorilla or orang, particularly in the contour and morphological details of the supraorbital and frontal regions. In these characters, indeed, they display a most interesting resemblance to primitive hominids such as *Pithecanthropus*.

The vast amount of material which has now been collected by Dr Broom and Mr Robinson (and which is still being collected) surpasses anything of the sort which has ever been known before. Not the least interesting feature of all the new discoveries is the abundant confirmation which they provide of the conclusions drawn by the South African scientists from their study of the first remains of the *Australopithecinae* which were found quite a number of years ago. Whether these ape-like creatures can be properly termed "missing links" depends, of course, on how this term is understood. At least it can hardly be doubted, particularly with all the new evidence which has been recently accumulated, that they come much nearer to the popular conception of a "missing link" than anything else so far discovered.

CORTISONE AND A.C.T.H. AGAIN

JUST over a year has passed since Hench and his colleagues¹ at the Mayo Clinic first announced the effect on rheumatoid arthritis of "Cortisone" and A.C.T.H. A symposium² from this centre measures the distance covered in the subsequent surge of exploration.

Hench³ confesses that how these substances work is still a mystery. What does seem clear is that their action is not on the aetiological irritant but on the tissue reactions to that irritant. Dr John R. Mote (whose remarks are summarised on another page) expressed the same thought last week at the first International Congress of Internal Medicine when he suggested that cells were "immunised against their environment". Hench points out that these substances can be credited with an impressive number of "firsts". They are the first natural agents by which has been demonstrated the potential reversibility of several diseases, including rheumatoid arthritis. They are the first agents which have shown real promise of affecting certain features of acute rheumatic fever and acute rheumatic carditis that are not influenced by salicylates. They are the first natural or hormonal agents found capable of consistently giving symptomatic relief and a temporary reprieve in the face of an intercurrent severe acute crisis of disseminated lupus erythematosus. Apart from adrenaline, they are the first hormonal agents with pronounced anti-allergic properties. They are the first which apparently have the power of suppressing certain ocular lesions that have previously been difficult to control and have produced much blindness. Finally, for the first time potent adrenal cortical hormones are available for long term studies of the psychological changes accompanying extensive physiological change.

Of 23 patients with severe or moderately severe rheumatoid arthritis⁴ who have been followed up for 7-14 months after administration of one of these hormones was discontinued, 8 had maintained 60-90% of their initial improvement, 5 had maintained about 50%, and the remaining 10 had maintained little or none. From investigation of 10 patients with rheumatic fever⁵ who were examined on average 5.9 months after dismissal from hospital, it was concluded that either cortisone or

A.C.T.H. can effectively suppress the acute manifestations of this disease, but when treatment is discontinued these manifestations will continue to reappear until the rheumatic state has come to its natural end. Whether either drug helps to prevent rheumatic carditis is not clear, but it does seem that they can greatly improve the condition of some patients with established carditis. In acute disseminated lupus erythematosus⁶ arthralgia, fever, eruption, and serositis are suppressed, and there is greater sense of well being with increased appetite and gain in weight. Ability to withstand stress and crises is also improved, and some degree of true remission may occur. Laboratory findings remain, however, abnormal, the pathological reactions of the tissues are unaffected, and relapse follows discontinuation of treatment. The administration of cortisone to patients with hay fever or bronchial asthma⁷ resulting from sensitivity to ragweed pollen always promptly relieved symptoms—rather more promptly in asthma than in hay fever—but once again the benefit ceased soon after treatment was stopped. In ulcerative colitis⁸ there is sometimes subjective relief, but no objective improvement as judged by proctoscopic and radiological examination. In acute leukaemia⁹ remission may be complete but is only temporary. In chronic lymphocytic leukaemia and in Hodgkin's disease remission is at best partial, and is again temporary. Ocular inflammation¹⁰ associated with arthritis appears to be controlled by cortisone, and the symptoms—and more slowly the signs—of vernal conjunctivitis are relieved. Evidence is accumulating that in glomerulonephritis¹¹ associated with oedema cortisone may produce a beneficial diuresis. In periarteritis nodosa and cranial arteritis¹² clinical remission and sometimes possibly improvement in the pathological process are evoked. As to psychiatric aspects,¹³ "the sudden and profound variation in the milieu intérieur which so markedly affects the patients' metabolic homeostasis is similarly disruptive of his psychological adaptation. The variety and degree of this disruption seem to be the resultant of many vectors". In Addison's disease¹⁴ cortisone given together with deoxycortone acetate has yielded excellent results, and cortisone appears to dispel the serious reactions that may follow radical subtotal adrenalectomy for Cushing's disease. In myasthenia gravis¹⁵ transitory improvement has been noted.

Sprague¹⁶ remarks in his summary that with few exceptions the conditions influenced by these hormones are not associated with clear hormonal deficiency. Thus, for benefit, hormonal excess must be created, and "it becomes necessary to find ways and means of dissociating the beneficial therapeutic effects of the hormones from their other physiologic effects". Whether this can be achieved is still uncertain. Meanwhile the therapeutic promise of these drugs seems to be greatest in acute or self-limiting diseases.

THE INDEX and title-page to Vol. I, 1950, which was completed with THE LANCET of June 24, is now in preparation. A copy will be sent gratis to subscribers on receipt of a postcard addressed to the Manager of THE LANCET, 7, Adam Street, Adelphi, W.C.2. Subscribers who have not already indicated their desire to receive indexes regularly as published should do so now.

INTERNATIONAL CONGRESS OF HÆMATOLOGY

THIS congress was held in Cambridge from Aug 21 to 26. The third of its kind, it was the first held outside the U.S.A., and it gave many of its 450 members their first opportunity of meeting their correspondents from other countries. It provided excellent facilities for "making the bibliography come to life."

THERAPY OF ANÆMIAS

The first session, with Sir LIONEL WHITBY, president of the congress, in the chair, led off appropriately with a talk by Mr LESTER SMITH, D.Sc., on vitamin B₁₂. He said that the molecular weight is now estimated at 1650 ± 100 , various bits of the molecule have been identified but a large part, including the place of the cobalt attachment, remains unknown. Three other chemically active related factors have been identified, but their chemical differences are not sorted out. Dr BYRON HALL (U.S.A.) reminded us that vitamin B₁₂ by mouth has little effect even in large doses, divided or daily. Dr GRACE GOLDSMITH (U.S.A.) thought that 4 µg injected daily gave results poorer than liver extract and reported failure with oral treatment, though in sprue and nutritional macrocytic anæmia 5-30 µg by mouth daily did evoke some response. She recalled that a good hemopoietic response has been obtained in pernicious anæmia when 5 µg of B₁₂ is given orally together with a duodenal extract, but she did not mention what was the effect of the duodenal extract alone. Finally she suggested that vitamin B₁₂ may not maintain pernicious anæmia patients at proper blood levels for long periods.

Dr J. G. A. MCSORLEY recapitulated his published work on the isolation of materials with B₁₂ activity from sources such as faeces. He also pointed out that the vitamin left the leucopenia unaffected in four cases of pernicious anæmia, and five others had relapsed on 40 µg parenterally per month. Dr J. C. PATEL (India) had found among patients with tropical megaloblastic anæmia that those with free HCl in the gastric juice often respond to B₁₂ orally in doses of 20-600 µg daily, some of the achlorhydrics showed an irregular response, but in true pernicious anæmia there was no response at all. Dr L. WEISSBECKER (Germany) commended cobalt for the treatment of anæmia in infection, and oddly enough for Mediterranean anæmia.

In the discussion Prof P. A. OWREN (Norway) produced more evidence that vitamin B₁₂ is *not* the anti-anæmic principle and that responses to it are partial. He showed that the prothrombin concentration is low in untreated pernicious anæmia and remains low when B₁₂ treatment has raised the hæmoglobin, folic acid has the same effect, but some liver extracts will restore the picture. He also pointed out that abnormal hæmoglobin of foetal type remains, and macrocytosis persists, with B₁₂ treatment.

During a later session Dr O. LARSEN (Norway) described the occurrence in pernicious anæmia blood of large thin cells which he called macrocytes—in contradistinction to megalocytes which are large cells of normal thickness. It is these cells that cause macrocytosis persisting long after the mean cell volume becomes normal under treatment, they have a life span of 40-60 days, and a considerable proportion of their hæmoglobin appears to be foetal. Treatment with vitamin B₁₂, folic acid, and some commercial liver extracts fails to influence the macrocytes and Dr Larsen suggested that liver contains another factor necessary to produce a completely normal blood picture. This factor had been separated and is not hemopoietic in the usual sense.

Dr M. BEARD (U.S.A.) had a group of thirty-seven patients who were being treated with liver extract not

all satisfactorily. They were transferred to vitamin B₁₂ treatment, 30 µg monthly. At first they did well, the patients with low counts rising to normal levels. But after 7-11 months the counts fell and the M.C.V. rose again. Increase of B₁₂ up to 100 µg weekly had no effect, equally ineffective were supplements of folic acid, pyridoxine, iron, and ascorbic acid. Most of the patients had inadequate protein in their diet, and Dr Beard thought that a factor in liver protein might be necessary for full recovery in pernicious anæmia. Dr K. HAUSMANN (Germany) described the isolation, from many sources, of fractions with B₁₂ activity, and showed that some of the cobalt-containing pigments will support growth of appropriate lactobacilli, but are not clinically active.

Dr J. F. WILKINSON remarked that the dosage of B₁₂ is steadily on the upgrade and he now gives 20-60 µg weekly, but, even so, glossitis and poor counts persist in some cases. Allowance must be made for the big variation in individual requirement of active material in patients with pernicious anæmia, hence only reasonably large series of cases are useful for estimating dosage. Dr C. C. UNGLEY said he now gives a minimum of 60 µg weekly, increasing up to 200 µg if there are neurological complications.

ETIOLOGY OF LEUKÆMIA

Dr J. HOOGSTRATEN (Canada) felt that the evidence of tissue culture should make us pause before placing human leukæmias firmly among the neoplasms, though the evidence from animal leukæmias seems firm enough. Dr J. N. DAVIDSON had estimated deoxyribonucleic acid (DNA) and ribonucleic acid (RNA) in the blood and marrow cells in leukæmia. The amounts present per cell were roughly the same in normal and leukæmic cells—the figures are given in ten millionths of a microgramme. The ratio DNA/RNA falls in acute leukæmia when folic acid antagonists are given, and rises again when a relapse is on the way. Other papers were given by Dr L. VES (Germany) and Dr POLLI (Italy) on cytochemistry, Dr UNDRITZ (Switzerland) on mitotic abnormalities, and Professor CHEVALLIER (France). The discussion showed that little advance has been made in this subject.

HÆMOGLOBIN METABOLISM

Prof CARL MOORE (U.S.A.) said that studies with radioactive iron have confirmed that ferrous is superior to ferric iron for oral treatment, about 26% of an oral dose is utilised as hæmoglobin iron from ferrous salts but only 6% from ferric salts. The normal person absorbs 2-11% of an oral dose of iron, so the intestine is not completely selective. It is common practice to give ascorbic acid to patients with iron deficiency anæmia, and study of this practice shows that ascorbic acid assists absorption of iron from protein foods. Iron is excreted in appreciable amounts by various routes, including the sweat, in males the average daily loss is about 1 mg of iron, in women the figure is raised to 15-20 mg by menstruation. Iron has been shown to pass from mother to foetus. Finally Professor Moore made the welcome announcement that "easily split-off iron" is an artefact.

Dr I. M. LONDON (U.S.A.) said that by using N¹⁵ to label glycine (aminoacetic acid) which is specifically utilised for the synthesis of porphyrin and so hæmoglobin it has been found that the average life of the normal red cell is 120 days and that destruction follows a regular pattern over 100-150 days. In sickle cell anæmia the destruction pattern is quite random, in pernicious anæmia survival is short and destruction random, in polycythæmia vera there is an increased

it clear that the skull as a whole (as well as the dentition, which includes as usual a remarkably small canine) shows many differences from that of a gorilla or orang particularly in the contour and morphological details of the supraorbital and frontal regions. In these characters, indeed they display a most interesting resemblance to primitive hominids such as *Pithecanthropus*.

The vast amount of material which has now been collected by Dr Broom and Mr Robinson (and which is still being collected) surpasses anything of the sort which has ever been known before. Not the least interesting feature of all the new discoveries is the abundant confirmation which they provide of the conclusions drawn by the South African scientists from their study of the first remains of the *Australopithecine* which were found quite a number of years ago. Whether these ape-like creatures can be properly termed "missing links" depends of course, on how this term is understood. At least it can hardly be doubted particularly with all the new evidence which has been recently accumulated that they come much nearer to the popular conception of a "missing link" than anything else so far discovered.

CORTISONE AND A.C.T.H. AGAIN

JUST over a year has passed since Hench and his colleagues¹ at the Mayo Clinic first announced the effect on rheumatoid arthritis of 'Cortisone' and A.C.T.H. A symposium² from this centre measures the distance covered in the subsequent surge of exploration.

Hench³ confesses that how these substances work is still a mystery. What does seem clear is that their action is not on the aetiological irritant but on the tissue reactions to that irritant. Dr John R. Mote (whose remarks are summarised on another page) expressed the same thought last week at the first International Congress of Internal Medicine when he suggested that cells were 'immunised against their environment'. Hench points out that these substances can be credited with an impressive number of "firsts." They are the first natural agents by which has been demonstrated the potential reversibility of several diseases, including rheumatoid arthritis. They are the first agents which have shown real promise of affecting certain features of acute rheumatic fever and acute rheumatic carditis that are not influenced by salicylates. They are the first natural or hormonal agents found capable of consistently giving symptomatic relief and a temporary reprieve in the face of an intercurrent severe acute crisis of disseminated lupus erythematosus. Apart from adrenaline, they are the first hormonal agents with pronounced anti-allergic properties. They are the first which apparently have the power of suppressing certain ocular lesions that have previously been difficult to control and have produced much blindness. Finally, for the first time potent adrenal cortical hormones are available for long term studies of the psychological changes accompanying extensive physiological change.

Of 23 patients with severe or moderately severe rheumatoid arthritis⁴ who have been followed up for 7-14 months after administration of one of these hormones was discontinued 8 had maintained 60-90% of their initial improvement, 5 had maintained about 50%, and the remaining 10 had maintained little or none. From investigation of 10 patients with rheumatic fever⁵ who were examined on average 5.9 months after dismissal from hospital, it was concluded that either cortisone or

A.C.T.H. can effectively suppress the acute manifestations of this disease but when treatment is discontinued these manifestations will continue to reappear until the rheumatic state has come to its natural end. Whether either drug helps to prevent rheumatic carditis is not clear but it does seem that they can greatly improve the condition of some patients with established carditis. In acute disseminated lupus erythematosus⁶ arthritis fever, eruption, and serositis are suppressed and there is greater sense of well being with increased appetite and gain in weight. Ability to withstand stress and crises is also improved and some degree of true remission may occur. Laboratory findings remain however abnormal the pathological reactions of the tissues are unaffected, and relapse follows discontinuation of treatment. The administration of cortisone to patients with hay-fever or bronchial asthma⁷ resulting from sensitivity to ragweed pollen always promptly relieved symptoms—rather more promptly in asthma than in hay-fever—but once again the benefit ceased soon after treatment was stopped. In ulcerative colitis⁸ there is sometimes subjective relief, but no objective improvement as judged by proctoscopic and radiological examination. In acute leukaemia⁹ remission may be complete but is only temporary. In chronic lymphocytic leukaemia and in Hodgkin's disease remission is at best partial, and is again temporary. Ocular inflammation¹⁰ associated with arthritis appears to be controlled by cortisone and the symptoms—and more slowly the signs—of renal conjunctivitis are relieved. Evidence is accumulating that in glomerulonephritis¹¹ associated with a dema cortisone may produce a beneficial diuresis. In periarthritis nodosa and cranial arteritis¹² clinical remission and sometimes possibly improvement in the pathological process are evoked. As to psychiatric aspects,¹³ "the sudden and profound variation in the *milieu interieur* which so markedly affects the patients' metabolic homeostasis is similarly disruptive of his psychological adaptation. The variety and degree of this disruption seem to be the resultant of many vectors." In Addison's disease¹⁴ cortisone given together with deoxycortone acetate has yielded excellent results, and cortisone appears to dispel the serious reactions that may follow radical subtotal adrenalectomy for Cushing's disease. In myasthenia gravis¹⁵ transitory improvement has been noted.

Sprague¹⁶ remarks in his summary that with few exceptions the conditions influenced by these hormones are not associated with clear hormonal deficiency. Thus, for benefit, hormonal excess must be created and "it becomes necessary to find ways and means of dissociating the beneficial therapeutic effects of the hormones from their other physiologic effects." Whether this can be achieved is still uncertain. Meanwhile the therapeutic promise of these drugs seems to be greatest in acute or self-limiting diseases.

THE INDEX and title-page to Vol I 1950, which was completed with THE LANCET of June 24 is now in preparation. A copy will be sent gratis to subscribers on receipt of a postcard addressed to the Manager of THE LANCET, 7 Adam Street, Adelphi, W.C.2. "pro convertin" After the first part of the session, which was severely technical, the second part was devoted to hæmophilia.

Dr R G MACFARLANE said that though it is reasonably certain that the clotting defect in hæmophilia is due to deficiency or inhibition of a plasma factor, we still do not know what it is—apart from its connection with the globulin fraction. He therefore avoided the use of terms like thromboplastinogen as too precise. Compared with normal blood, hæmophilic blood is less sensitive to the action of thromboplastin, the insensitivity can be corrected by the addition of normal plasma, which presumably contains the thromboplastin co factor, this co factor is particularly important when thromboplastin levels are low, as they are in normal clotting. There is evidence, too, that the deficiency of this globulin factor is accentuated by a defect in the albumin fraction of hæmophilic blood. He also pointed out that in whole blood clotting, as distinct from artificial mixtures of "factors," thrombin is rapidly destroyed, and that normally thrombin formation keeps ahead of destruction, but in hæmophilia the rate of thrombin formation is slow and does not keep ahead of destruction, so the blood appears unusually stable.

Dr P D FEISLY (Switzerland) emphasised the platelet abnormalities, and Dr A FIEHRER (France) discussed the abnormal albumin in hæmophilia.

Dr K M BRINKHOUS (USA) described a most interesting hæmorrhagic disease seen in a breed of setter dogs. It has now been studied for 4 years and resembles human hæmophilia very closely. The mode of inheritance, as tested by breeding experiments, is the same. By mating an affected male with a proved female carrier, affected females were obtained—as theory required. Attempts to breed from these females failed because there was always intra uterine hæmorrhage. The clinical picture is like that of human hæmophilia, with hæmarthroses and large subcutaneous hæmorrhages prominent, and the abnormalities of blood clotting are precisely the same as in human hæmophilia. The blood of the known transmitter females has been carefully examined, but no abnormality or indication of the transmitter state has been found. Further work on these animals is projected, but they are not easy to keep alive.

Dr V BIANCHI (Italy) startled his audience by stating that it is possible to keep the blood of a hæmophilic person normal by injecting 3 ml. of fresh human plasma daily. Dr C MERSEY (South Africa) described the re-examination of two female "bleeders" from a hæmophilic family in which there had been a first-cousin marriage. The plasma of these women would not correct the slow clotting of known hæmophilic blood, and it was concluded that they were true hæmophiliacs.

In the discussion, Dr Bianchi's methods were destructively criticised and it was stated that at least 50 ml. of fresh human plasma is needed to correct the clotting defect of hæmophilic blood for 3 days, and the effects of 10 ml. pass off in 8 hours. Dr VAN CREVELD (Holland) showed that lyophilised heparin plasma gives better preservation of the anti hæmophilic globulin than citrated plasma. Professor OWREN thought that studies of the pro accelerator factor in the blood of female transmitters in hæmophilia did show abnormalities.

PURPURA

Prof A FONIO (Switzerland) gave a high speed account of the physiology and pathology of blood platelets, and Dr F KOLLER (Switzerland) showed two cases of purpura fulminans in scarlet fever that he attributed to factor V deficiency. Dr E L LOZNER (USA) spoke about the difficulties in treating primary thrombocytopenic purpura. There are some patients who do not respond to splenectomy, and some whose platelet level falls after a post splenectomy rise. He

noted that over the age of 15 there are nearly four times as many females as males, and also that babies from mothers who have had splenectomy may be thrombopenic. Thrombocytopenic purpura is often associated with puberty, menstruation, and pregnancy, and in both man and animals oestrogens have been reported to produce thrombopenia. All this suggested that there is an oestrogenic element in thrombocytopenia, and Dr. Lozner stated that ACTH has produced a remission in thrombocytopenic purpura, possibly by inhibiting oestrogen.

Dr H N ROBSON had observed capillary function in patients receiving ACTH treatment and found an increase in capillary resistance to rupture by negative pressure.

EXPERIMENTAL LEUKEMIAS

Dr J BICHEL (Denmark) presented results with tissue cultures which in his opinion showed that such preparations are of little use for differentiating between different cells in leukemias. Dr U HAERTEL (Switzerland) had given folic acid antagonists and benzimidazole, which reduces the white cell count in chronic myeloid leukemia—to patients and had studied the cells in the marrow by staining with pyronin at pH 4.9. He thought that these substances work by interfering with ribonucleic acid formation and by blocking mitosis in metaphase. Dr W JACOBSON, however, produced evidence that folic acid antagonists do not do either of these things. He interpreted his results as showing that they prevent the shedding of ribonucleic acid from the chromosomes in telophase.

BLOOD GROUPS

The final day was dominated by the immunohæmatologists, whose papers were often for the expert only.

Dr J VAN LOGHEM (Holland) discussed the relative importance of the twenty nine known blood factors and some points in the organisation of transfusion services. Dr A E MOURANT, dealing with blood transfusion services in non European countries, suggested that the money needed for setting up all the facilities for catching the odd Rh incompatibility might well be better devoted to other health purposes such as the control of malaria and hookworm, this applied especially to Asia.

Dr A S WIENER (USA) gave a spirited account of the application of Rh-Hr blood tests to disputed paternity cases and to sorting out inadvertently mixed twins. The correctness of his conclusions was, he said, usually confirmed by the repentant mothers, and so evidence for the support of his theory of Rh Hr inheritance was obtained. He pointed out that in New York, by using ABO, MN, and Rh Hr tests, a man stood a 50% chance of being proved not the father when wrong. Fully accused and apparently the courts can order—and appreciate the value of—blood tests.

Dr P MOUREAU (Belgium) gave a bilingual account of a man proved innocent by the group tests, including the "S" factor. Dr R SANGER described the blood of a person of unimpeachable pedigree, with a second cousin marriage at an important point, who had no detectable representative of the C or E series of allelomorphous antigens in her serum. Her group was therefore -D / D. All her children had been either stillborn or erythroblastic. Both Dr WIENER and the supporters of Fisher's theory maintained that this occurrence provided firm proof of the correctness of their respective ideas on the inheritance of Rh subgroups.

* * *

In conveniently placed rooms there was an exhibition of books, apparatus, and commercial products, and some demonstrations among which Dr S MOESCHLIN's set of colour photograph transparencies from spleen puncture material was particularly good. The high spot was the demonstration of rival red-cell-counting machines, whose

production of cells with a normal life span. Also using N^{15} , it has been found that 10-15% of the bile pigment excreted in the faeces comes from sources other than circulating red cells, in pernicious anaemia the figure is 40%, and in a patient with congenital porphyria whose red cells had a normal life span the figure was 30%. The sources of this pigment are not clear, but hæm not bound to globin may be one of them.

HYPERSPLENISM

Dr T S EVANS (U.S.A.) showed that in giant follicle lymphoma the anaemia can be attributed to splenic overactivity, as the condition is relatively benign, splenectomy for the relief of the anaemia is a logical step and all his three patients so treated did well. Dr P S HAGEN (U.S.A.) held that the anaemia in leukaemia is hæmolytic and can be attributed to hypersplenism. Eight patients, in whom the anaemia rather than the leukaemia was the important disability, were treated by splenectomy, they were not cured, but their need for supporting blood-transfusions was sharply reduced. The Coombs test was positive in only one case and remained positive after splenectomy.

Dr R O M BERLIN (Sweden) put the matter on a scientific basis by showing that the survival of the red cells in these patients is much reduced (to 35 days or less), the reduction runs roughly parallel with the degree of splenomegaly. After splenectomy, the survival-times of the red cells were much prolonged. Again, the patients were not cured, but transfusions were needed only infrequently. The presence of blast cells was an absolute contra indication to splenectomy.

Dr KISSMEYER NIELSEN (Denmark) had found that ligating the splenic vein in rabbits permanently reduces the granular white cells in the blood but has no other lasting effect, the marrow in particular was unaffected. The animals so treated did not show the anaemia, granulocytopenia, and thrombopenia that toxic effects such as infection with tubercle bacilli produce in the normal animal. The results suggested that the spleen acted on the peripheral blood rather than distantly on the bone marrow.

At the end of a long session Dr W DAMESHEK (U.S.A.), the chairman, announced that he had seen no good results in eighteen splenectomies done for leukaemia, and he feared that the discussion had confirmed his growing opinion that hypersplenism was a romantic subject devoid of scientific truth.

HÆMOLYTIC ANÆMIAS

Dr DAMESHEK explained his theory that the factor common to symptomatic and idiopathic hæmolytic anaemias is the presence of abnormal antibodies in the plasma. Modern techniques, like the use of albumin solutions and the Coombs test, have helped to detect these antibodies in an increasing proportion of patients. He outlined a theoretical scheme to explain how the hæmolysis occurs and concluded that for treatment there are four lines of approach: (1) to check antibody formation, (2) to neutralise antibody, (3) to modify the red cell membrane, and (4) to remove the spleen. Only the first and last are practicable at present. To stop antibody production, nitrogen mustard has been used, but a response was obtained in only one out of four patients. Splenectomy was performed because the spleen is the destroyer of spherocytes—i.e., red cells affected by hæmolysins. Dr Dameshek thought little of the idea that the spleen inhibits erythropoiesis in the marrow. Splenectomy is not, however, a complete answer, of forty six patients so treated, full recovery occurred in twenty one only. Experience with leukaemia, even when autohæmolysins were present, was uniformly unfavourable. A C T H has been tried, since it is said to influence antibody formation, but the results were

Dr E WITEBSKY (U.S.A.) recommended a mixture of normal serum and 30% serum albumin for detecting antibodies and pointed out that patients with acquired hæmolytic anaemia often develop unusual antibodies against Rh antigens. Dr W H CROSBY (U.S.A.) showed that in paroxysmal nocturnal hæmoglobinuria the plasma contains a heat labile factor that hæmolyzes the defective red cells only when it has been activated by thrombin. The blood clotting factor "plasma Ac globulin" is similarly activated to "serum Ac globulin" (factor VI) by thrombin, so possibly the clotting and hæmolytic factors are identical. If so, it might be rational to prevent hæmolysis by using anticoagulants. Dicoumarol did, in fact, diminish hæmolytic activity temporarily, but whenever it was stopped a hæmolytic crisis followed.

HODGKIN'S DISEASE AND LEUKÆMIAS

Dr S MOESCHLIN (Switzerland) argued that Hodgkin's disease should be treated like a neoplasm by extirpation of the primary focus followed by application of X rays and nitrogen mustard, he had three patients treated this way who had lived 5-10 years without relapse.

In leukaemia Dr J M STICKNEY (U.S.A.) had used up to 200 mg of A C T H and 300 mg of 'Cortisone' daily for adults, and 50-70% of these doses for children, courses of 20-30 daily doses were given. The excretion of 17 ketosteroids was used to check the activity of the material used, A C T H increasing and cortisone decreasing the excretion. The usual side effects were seen, but no mental troubles. Of eighteen patients with acute leukaemias, two had complete remissions but were now leukaemic, the other sixteen had died. At necropsy focal areas of necrosis were found in the marrow with islands of leukaemic cells, elsewhere erythropoiesis was active, the usual leukaemic infiltration of liver and kidneys was present and unaffected. In chronic lymphatic leukaemia, 2 g of cortisone caused shrinkage of liver, spleen, and lymph glands, but the blood and bone marrow remained leukaemic. In three cases of Hodgkin's disease results were poor. The best remission, lasting 16 weeks, occurred in an adult of 31 with myeloblastic leukaemia, but he died 10 weeks later when a second course had no effect. This resistance to second courses was lamentably frequent.

Dr DAMESHEK reported results in twenty five cases of leukaemia and five of lymphosarcoma with similarly disappointing results. As much as 60-80 mg of A C T H was needed daily, remissions were seen only in children, and then the side effects were serious and disfiguring. In two patients with myeloma, 40 mg of A C T H daily stopped pain and reduced the hyperglobulinaemia for 5 months. On the whole, Dr Dameshek considered that A C T H is not of practical therapeutic value in leukaemias. Dr VIDEBAEK (Denmark) had five similar cases.

In the discussion Dr WEISSBECKER confirmed the uselessness of A C T H in Hodgkin's disease, Dr SUZMAN (South Africa) pointed out that A C T H may light up dormant tuberculous foci, Dr HOOGSTRATEN had eight patients, Dr SHIMKIN (U.S.A.) ten patients, and Dr SEFSON three—all with poor results. Finally, Dr L FOURMAN pointed out that injected A C T H is rapidly destroyed and excreted and should therefore be given in small divided doses, not daily. The session closed with better therapeutic results reported by Dr E E OSGOOD (U.S.A.) with total body irradiation by X rays or P^{32} by Dr J H BURCHENAL (U.S.A.) with folic acid antagonists including 2, 6 diaminopurine, and by Dr P BJERRE HANSEN (Denmark) with urethane.

CLOTTING OF BLOOD

During a field day for the conglutinationists, the uninitiated learnt with horror that more new, or renamed, "factors" are on the way, like "pro accelerin" and

the characteristics of Cushing's syndrome. For the syndrome he had described Professor Zondek suggested the name 'diencephalopathia vascularis'.

STREPTOMYCIN

In a paper submitted to members of the congress ETIENNE BERNARD and B. KREIS (Paris) discussed the development of resistance to streptomycin. In a small series of cases they had shown that heavy dosage (2-5 g.) hastened the appearance of resistance. They had observed, too, 'dissociated' resistance in the same patient according to the lesions from which the organisms were obtained. They had also confirmed the rarity of resistant organisms in meningitis treated even for long periods with streptomycin, and they had found the same, though to a lesser degree, in military tuberculosis. On the other hand, with cavitation or with purulent effusions, resistance was common, and from this they deduced that the more abundant the organisms in lesions, the more readily would resistance develop. Not all lesions due to sensitive organisms were cured by streptomycin. Perhaps this was due to too low a concentration, or to local inactivation, of the antibiotic, but the main factor was probably the structure of the lesion or inadequacy of the patient's defence mechanism. No undoubted aggravation of the disease had been seen to follow streptomycin treatment. For the patient the real danger of streptomycin resistance was that he would eventually be deprived of an irreplaceable weapon for society: the risk was that as infections with resistant organisms spread, the benefits of this great advance would gradually recede to vanishing-point.

R. DUBOIS MANNE (Brussels) urged that tuberculous meningitis should now be regarded as curable, since 31% of patients survived after streptomycin treatment had been discontinued for a year. K. TODOROVITCH (Belgrade) held that in tuberculous meningitis streptomycin was of the greatest value when given in moderate doses by combined intramuscular, lumbar, and cisternal injections. JEAN TAPIE (Toulouse) underlined the importance of early and prolonged treatment by intramuscular and intrathecal injection, the latter being indispensable in the acute stage. In practice the risk of resistance need hardly be considered when the response was unsatisfactory: it was more important to seek a pathological cause such as spinal block or calcified tuberculoma. The prognosis, except where the response was immediate, depended on the extent of caseation and on whether or not basal exudate interrupted the C.S.F. circulation.

SOME FURTHER TOPICS

Radioactive substances.—RENE FAUVERT and ANDRÉ LOVERDO (Paris) had investigated the movements of the sodium ion in health and disease. A mathematical study of the diffusion-curves for Na^{24} injected into the bloodstream showed that it was possible to distinguish four phases in ionic diffusion, characterised by four distinct exponential curves. These data had been used in studying the rate of diffusion through the capillary walls and in measuring the volume of extracellular space in normal and pathological states.

Alcoholic cirrhosis.—RENE CACHERA, MICHEL LAMOTTE, and SUZANNE LAMOTTE-BARRILLON (Paris) had recorded by repeated biopsies the histological state of the liver in 82 alcoholics. Fatty infiltration sometimes massive, was the dominant histological finding in alcoholic cirrhosis without clinical signs. Liver-function tests in these cases usually gave normal results. A further and more detailed study on 40 alcoholics had shown that the evolution of the liver changes was very variable. It was possible for massive infiltration to disappear: the factors aiding this process were abstinence from alcohol, attention to diet and administration of hypotrophic substances.

The liver condition was an overdeposition of fat and not a fatty degeneration. In chronic alcoholism, as in experimental fatty infiltration, the eventual cause was probably a deficiency of hypotrophic factors, but this might not be the whole explanation, for in some cases of cirrhosis there was neither undernutrition nor alimentary disorder. The endocrine system, which was known to be affected in chronic alcoholism, might play a part in mobilising reserves of tissue fat, which was then transferred to the liver.

Postabortal, anuria.—PASTEUR VALLERY-RADOT, PAUL MILLIEZ, CLAUDE LAROCHE and LOUIS MOREAU (Paris) remarked that the clinical picture of postabortal anuria was always the same, whatever the causative organism or toxin. The critical period was between the 8th and 20th days. If the patient survived long enough for regeneration of the tubular epithelium to take place, recovery was complete, and renal function returned fully to normal in 6-12 months. Histological studies showed that the glomeruli and the afferent and efferent vessels were unharmed but were empty of blood, and the tubular changes were not generalised, especially in the early days. These tubular lesions did not account for the whole picture. The persistent albuminuria, and the absence of blood in the glomeruli and in the afferent and efferent vessels, seemed to point to vascular spasm. The resulting renal anoxia was perhaps the cause of the tubular lesions and of the acidity of the urine, which favoured the precipitation of destroyed hæmoglobin in the kidney.

Relation between tuberculous infection and tuberculous disease.—J. HEMBECK (Oslo) who had observed 9000 Norwegian subjects for an average of 11 years, held that morbidity and mortality were much higher when the primary tuberculous infection was massive and long-continued than when it was small and brief. Morbidity was also increased by superinfection.

Arteriovenous anastomosis in the treatment of obliterative arteritis and of hypertension.—C. LIAN and H. WELTI (Paris) had developed a technique of lateral anastomosis between the femoral artery and vein, followed by ligation of the vein at its proximal end, in the treatment of obliterative arteritis of the lower extremities. They suggested a trial of this technique, though without ligation of the femoral vein, in arterial hypertension with a high diastolic pressure.

Coagulation-time.—A new method of measuring blood coagulation time was described by ANDERS KRISTENSON (Stockholm). This method was based on changes in the viscosity of blood placed in a rectangular vessel in which was suspended a pendulum. The resulting changes in the swing of the pendulum were recorded photographically on a moving film and thus a coagulation 'profile' could be obtained. This profile was different in the normal and in certain pathological conditions.

Sheep-cell agglutination test.—In collaboration with KARL SCHLOSSMAN, NANNA SVARTZ (Stockholm) had modified this test the essential feature being that all agglutinins against normal sheep cells were absorbed before the test with sensitised sheep cells was carried out. Sheep-cell agglutination with a high titre had been demonstrated in about 90% of cases of rheumatoid arthritis, and the test was only rarely positive in other diseases. Neither A.C.T.H. nor cortisone had any effect on this reaction.

REPORTS

The programme included, as well as medical films and clinical demonstrations, nearly two hundred different papers. These have appeared, in whole or in summary, in the *British Medical Journal* (Sept. 9), the *Semaine des Hôpitaux* (Aug. 30, Sept. 2, 6, and 10), the *Schweizerische medizinische Wochenschrift* (Sept. 9), and a special issue of *Acta Medica Scandinavica*.

extraordinary complexity was hidden under smooth façades. As these instruments cost about £500 apiece, they are unlikely to be popular just yet, and they are in fact still experimental.

* * *

When, after five days of almost continuous talking, the exhausted delegates separated, they must all have

felt that it had been a very useful conference, and were correspondingly grateful to Sir Lionel Whitby and Dr Martin Hynes and their staff who had done most of the organisation. Their satisfaction was tempered by regret that few are likely to surmount the obstacles in the way of reaching Buenos Aires for the next conference to be held in 1952.

INTERNATIONAL CONGRESS OF INTERNAL MEDICINE

IN medicine holism is often praised but seldom practised, and the courage of those who sponsored this congress, dedicated to the whole vast field of internal medicine, was highlighted by the international congresses on cardiology and psychiatry which preceded and followed it in the same capital—Paris.

The International Society of Internal Medicine was brought into being at a meeting attended by representatives of 19 nations at Basle on Sept 27, 1948. The initiative came largely from Prof Nanna Svartz, of Stockholm, and Prof A. Gigon, of Basle itself. No doubt the founders were encouraged by the success of conferences on internal medicine held from time to time in Switzerland with visitors from one or other of the countries of Europe, and Professor Gigon will be warmly remembered for his part in the profitable British Swiss conference of 1946. But what of a world conference, where neither subjects nor speakers could be so assiduously preselected?

In the event the enterprise succeeded. Some 1000 doctors from 46 nations were present at the Paris congress, from Sept 11 to 14. The defects were those common to most international meetings of this sort. Not all the papers maintained the prevalent high standard, not all the speakers put in an appearance, the agenda was somewhat over full, speakers often insisted in cramming an hour's speech into their allotted minutes, and the language bar was often evident. When the second congress is held in London in 1952 it might be well—supposing that the official languages remain English and French—to arrange for simultaneous translation, delivered through earphones, into the second language—an arrangement which proved highly satisfactory at the 1946 Basle conference. Alternatively, a brief summary could be given in the second language after each speech, printed summaries, even when available, are not always informative. This device proved effective at last year's meeting of the International Hospital Federation, though few could match the skill and tact then shown by Prof René Sand in reducing speeches to manageable proportions.

PRESIDENTIAL ADDRESS

In his address at the opening of the conference, Prof A. LEMIERRE, the president, recalled that the last world congress on internal medicine held in Paris—this was in 1900—was attended by Rudolf Virchow and Ivan Pavlov. None could doubt the need for the specialisation which had since become more and more evident, but few would applaud the ever firmer division between the growing number of specialties. To this day the tradition in France was that those who were to have charge of hospital beds must first gain a thorough grasp of all branches of medical pathology, thereafter it was time enough for them to turn to the specialty of their choice. Furthermore, in France accession to a chair in a clinical specialty was often preceded by temporary occupation of a chair in a general subject.

ENDOCRINOLOGY

Adrenocortical function—JOHN R. MOTE (Chicago) contributed a film illustrating dramatically the effect of adrenocorticotrophic hormone (A.C.T.H.) on the general

and local condition in a case of burns. The film showed a man with severe burns involving 70% of the body, with extensive exposure of muscle. With A.C.T.H. treatment pain was absent, there was no oedema, no fever, no disturbance of the electrolyte balance, and no anaemia at any stage, and the wound did not become infected. At the tenth day the patient walked without discomfort. Pinch grafts applied at the 41st day took, with one exception, and epithelisation was quickly completed. Earlier, Dr Mote had suggested that features of the action of A.C.T.H. were that it inhibited pain and fever. In all diseases where A.C.T.H. or 'Cortisone' were effective these substances were, he suggested, preventing damage to cells, cells were "immunised against their environment." By stimulation of the adrenal cortex it was possible for general peritonitis to be present without symptoms or signs, and similarly poisoning by snake or spider gave rise to no symptoms.

J. M. CARLISLE (New Jersey), speaking on the clinical uses of cortisone, emphasised the need for a rigid schedule of dosage, with gradual withdrawal. Cortisone was effective when given by mouth, but it should be administered first by injection, reserving the oral route for maintenance doses. Cortisone must be of the proper particle size, and some of the earlier work, undertaken with large particle cortisone, should be repeated using the better small particle substance. This should be kept at room temperature, below which it might deteriorate through formation of larger particles. Cortisone should be used with respect, in rheumatoid arthritis close attention should be given to diet, orthopaedic measures, and a proper balance of rest and exercise. Lately it had been used in toxæmia of pregnancy and in subdeltoid bursitis.

Among the papers on the action of cortisone and A.C.T.H. was one by B. OLHAGEN (Stockholm), who had found by electrophoretic analysis that in various diseases, and especially in rheumatoid arthritis, these substances evoked profound changes in the plasma components, with a general decrease of protein and a return towards a normal pattern. When treatment was discontinued changes in globulin reappeared before any other indication of relapse.

Deoxycortone—RÖLF LUFT and BJÖRN SJÖGREN (Stockholm) had found that in healthy subjects the administration of 20 mg deoxycortone acetate and 10 g sodium chloride daily caused a mean increase in blood pressure of 15 mm systolic and 10 mm diastolic, this increase was statistically significant. In hypotensive subjects the effect was the same, and postural hypotension had been successfully treated with deoxycortone in pellets. In the kidney deoxycortone produced an increased glomerular filtration rate but no change in renal blood flow.

Vascular changes in pituitary diencephalic lesions—H. ZONDEK (Israel) had observed in many patients of "pituitary" type minor vascular changes consisting in either vasoconstriction or vasodilatation, and clinically manifested by collapse, epileptiform attacks, migraine, anginal attacks, or angiospasm in the extremities, in one case there had been reported intestinal hæmorrhage. In no case was the blood pressure increased, nor was there any evidence of arteriosclerosis. No case showed

Letters to the Editor

TUBERCULOSIS

SIR,—The means of treating tuberculosis successfully have in many respects improved during the past few years. Favourable factors include

- 1 The gradual improvement of housing in many areas and the quicker supply of suitable shelters in which patients can be accommodated at home
- 2 The advent of chemotherapy and antibiotics
- 3 The easier practice of some active measures such as phrenic crush and artificial pneumoperitoneum
- 4 The wider use of portable equipment

Moreover general practitioners are more aware of early symptoms of the disease, and young doctors have been better instructed about diseases of the chest.

The present emergency is only partly due to the shortage of nurses and domestic staff in sanatoria, and it could be overcome if chest physicians were enabled to make full use of the other resources now at our disposal. The value and practicability of domiciliary treatment in a large proportion of cases is now clear. Where a patient, after a period of bed rest at home, seems likely to benefit from more active treatment such as phrenic crush or artificial pneumoperitoneum, this is feasible with a little organisation. Apart from the surgeons in the chest units, many surgeons in general hospitals are now willing to perform a phrenic crush as outpatient treatment, if they can rely on proper aftercare by the chest physician. The plan is already working well in some areas, and could be put into practice on a far larger scale. Artificial pneumoperitoneum can easily be induced under radiological control at the chest clinic, and can be continued by refills given in the patient's home. Now that these less hazardous methods are available, artificial pneumothorax, for which, ideally, the patient should be admitted to hospital or sanatorium, is less often required as the initial therapeutic approach.

But proper domiciliary treatment is impossible without proper equipment and enough health visitors and medical assistants. Those who, like myself, have visited clinics in several counties know that at present many are unfit to undertake active treatment on any large scale. Many still lack X-ray facilities and so cannot carry out refills; they depend on the already overburdened radiological department of a nearby hospital, which is continually pleading for fewer requests for radiographic examinations. In some regions it is impossible to arrange for tomograms within a 30 mile radius—these and other special radiological investigations may take anything up to four months to get done. Where there are X-ray plants, it often happens that the frame cannot be tipped or turned, which means that investigations with the patient in a recumbent or other unusual position simply cannot be made. I cannot help thinking that it would be more profitable to attach mass radiography units to clinics which lack X-ray plants, and use them for the examination of patients referred to the chest physician on medical grounds, than to employ them in the detection of disease in symptomless industrial workers.

Bronchography is carried out in but a few chest clinics. A large number of clinics have no proper aspiration sets, and many do not even possess a two way or three way syringe—not even a three way tap and adaptors, though these can be obtained for a few shillings. As a result, the chest physician suddenly called on to aspirate pleural fluid has to undertake all kinds of manipulations to avoid letting air into the pleural space. Another vital tool more often absent than not is a tension pneumothorax set. In one clinic I have seen, there are no X-ray facilities (and therefore no refill sessions), no sphygmomanometer (and therefore no blood pressure readings), no aspiration set, and no syringes or needles for taking blood, more

over the examination couch is in a lamentable condition. Clinics such as these cannot be justified in the light of modern requirements.

If a final breakdown of the tuberculosis service is to be avoided, the only possible policy is to bring the chest clinics up to standard, equip them with the tools needed, and staff them with personnel who know how to use them. The tuberculosis death-rate of nearly 400 per week is serious enough, but it is far more serious that thousands of living tuberculous patients should be lingering about, gradually deteriorating, and desperately awaiting some move towards their cure. Now is the time for the chest physician to initiate treatment in the patient's home whenever possible, just as any modern practitioner facing a patient with cardiac failure would not hesitate to administer digitalis or a diuretic almost at once. Chemotherapy, antibiotics, phrenic crush, and artificial pneumoperitoneum have been given to us as very helpful weapons in domiciliary treatment, which if intelligently applied can produce most gratifying results.

M D

TOBACCO AND LUNG CANCER

SIR,—The leading article under this heading in your issue of Aug. 12 suggests some comments.

1 The investigation of Passey and Holmes,¹ published 22 years ago, is brought forward once again to support the view that we do not know whether any real increase in cancer of the lung is occurring at the present time. J. A. Heady and the writer² have suggested that anyone arguing thus "is placing upon the material of Passey and Holmes a significance which it is not fitted to bear. For many years some students of this subject have wondered whether the (alleged) absence of any evidence in their data of an increase in cancer of the lung was not due to the fact that the great bulk of this increase took place after the period studied by Passey and Holmes." Between the last year of that period (1928) and the latest for which figures are obtainable (1948), the deaths attributed annually to cancer of the lung in England and Wales rose 10.4 fold in men (814 to 8500) and 5.6 fold in women (314 to 1755). Whatever may be thought of the reality of this increase the question can hardly be settled by data obtained before it began; the changes stated in the article in question to have occurred in other countries are surely irrelevant.

2 Your article states that "Kennaway and Kennaway³ assessed the apparent increase in this country (on which all authorities agree) and concluded that it is probably real—at least in part." The paper in question collects evidence from which the reader might form his own opinion, but this conclusion is not drawn.

3 The leading article selects for especial emphasis the cancer of the lung in the miners of the Erzgebirge, and in asbestos workers. If any enumeration of industrial forms of lung cancer is being attempted, the latest collection of data from the chromate industry⁴ should be mentioned.

All workers in cancer research will hope that Professor Dungal, whose article also appeared on Aug. 12, will give us more data from his very valuable material. The standard of living, and especially of nutrition, in Iceland is high, and the factors of social stratification, industrialism, and atmospheric pollution are quite different from those in many of the countries from which our statistics of cancer are drawn.

In England Now

A Running Commentary by Peripatetic Correspondents

"I find it hard to believe that these scientific folk reading papers at this World Congress of —ology are world leaders in their specialty and clever men. Most of them are pathetically inefficient at what they are at present doing. They come here to 'sell their goods,' their ideas and results, to their fellow —ologists, but they don't do it." So spoke a bright young thing, attending on an obscure special job. She had previously floated about the borders of film and radio work in the section of "clarity-production." She went on "The great majority of English speakers are inaudible to four-fifths of their audience. They imagine they are speaking to the audience, but they should be talking into the mike. Watch the audience. After two minutes they begin to look about, to make pretence of reading a programme, to pull out a book. Why don't the speakers rehearse and again rehearse, like an invited radio speaker, and why don't the authorities tell every speaker to SPEAK TO THE MIKE? As for the subject matter for their slides, of course I didn't understand any of it, but even I could see that sometimes they had two dozen statements on one slide. Think of the silent films. An average audience takes nearly a minute to grasp one fact put on the screen in eight words. To present complicated slides on the screen should be a penal offence. And as for the foreigners talking English! No man ought to dare to give a paper in a foreign tongue unless he grew up with that tongue, and is so expert that he could join a Secret Service and go to a foreign country expecting to be taken for a native. Surely your authorities could provide the foreigner with a prominent seat on the platform while a trained announcer reads his paper for him. And couldn't the authorities make certain the hall is in almost complete darkness for a minute when a slide is being shown. The speaker's reading light should be a glimmer. And another thing, 'Who is speaking?' I heard that question at the back of the hall at least a dozen times. Surely every speaker's name and country should be written large and plain on a blackboard?"

Fortunately I am trained to quick action in emergency. My instant invitation to a drink successfully dammed the flow.

* * *

It seems that more volunteers are needed for Eilean nan Ron, the little Scottish island where a common-cold research project is in progress, for this notice has appeared in the Medical School:

"Any student who wishes to participate in this research, and who also would like a holiday in a remote island with a cold in the head, should hand in his name to the secretary, Department of Mental Health."

* * *

At the symposium on formularies during the British Pharmaceutical Congress in Glasgow, it was interesting to hear the frank and well-informed criticism of some of our prescription writing, and of the main reason of its failings—namely, the dominance in medical schools of pathology and diagnosis over therapy. One medical teacher was said to have held that students need not know the doses of drugs. Enough that mixtures should be compounded by the pharmacist so that one unit gave a weak and two units a strong dose! Economical patients receiving 10 oz of a preparation with a dose of 1 drachm are apt to pass on the unused portion to a friend, and one speaker said it was a commonplace in his profession that the Fleet could be floated on wasted medicine. Another pointed out the menace of the domestic teaspoon as a measure, especially with children, and he also deplored the common use of even more erratic measures due, he said, to our failure to inform patients of the need for accuracy. The public took a rap or two as well, for the habit some have of drinking out of the bottle, and for their belief that if a spoonful three times a day is good, two spoonfuls six times a day is four times as good, or even better. Unimaginative prescribing of nauseous draughts for children was also

criticised. Why did we not make more use of black currant and rose-hip syrups? Why not indeed? Then the discussion touched lightly on *mist diabolica*, used, you will recall, to discourage the hypochondriac medicine addict. Some patients joyfully came back for more, for it was the "strongest stuff I've ever had." This I can confirm, even though our hospital's version was mainly asafoetida and valerian flavoured with a little paraldehyde.

On me the discussion had a tonic effect, and I realised as never before what good allies we have in the pharmacists.

* * *

Holidays abroad have brought home to me the important part played in any language by the meaningless phrases we employ automatically in our mother-tongue about such topics as the weather. My command of German is adequate, but such remarks as "Mahlzeit!" from the waitress or "Viel Vergnügen!" from the Gasthof proprietor always catch me, linguistically, on the wrong foot. "Danke schön!" soon becomes monotonous as a rejoinder, and while I am groping after eloquence the opportunity passes, leaving yet another foreigner convinced of stony British reserve and disillusioned as to the practicability of Western Union.

But how blissful, how restful to be in Yugoslavia where I can't speak a word of the language. No ruminating over half-understood phrases, while the next few sentences slip past, none of those repeated interjections of the local equivalent for "Yes," uttered with what one hopes is an expression of lively intelligence. Instead, a fatuous grin and the self-explanatory designation "Engleski" melt the hearts even of customs officials and invariably call forth kindness and solicitude as for the mentally afflicted. Unfortunately, they also at times call forth one of those busybodies who profess to talk foreign languages, but if I stick to English I am usually able to discourage them in the end.

And the children seem remarkably quiet and well-behaved. Perhaps even the Yugoslavs draw the line at offspring who answer back in Serbo-Croat.

* * *

In the State of New York a medical career of great promise was interrupted last week by a sentence of one year in a county penitentiary. For five years the victim had successfully held resident posts in various hospitals along the Eastern seaboard, and everything went smoothly until he fell behind with payment for a car. Then the police interfered, and the upshot was the discovery that he had never been to a medical school. In retrospect, of course, it is perfectly obvious that this man was no ordinary doctor. *The New York Times* of Sept. 14 tells us that he is "short, stocky, and suave," with a black moustache and spectacles. Well, so are a lot of us, though perhaps fewer are, as one hospital administrator said of him, "very pleasant and impressive." But listen to this. He had "an extraordinary knowledge of English and Latin medical phrases." What a give away! Then again he had just been serving for four months as senior resident physician "without a single medical error," and the State police were unable to find that he had ever "committed a medical misdeed in numerous operations." What a blunder! There's only one thing for it. We must have a controlled investigation in which one half of a hospital staff will be qualified in the old-fashioned way and the other half will be self-styled doctors. The patients will be the judges. The qualified half will get a chance of learning to be "very pleasant and impressive." The rest of us will await the outcome with ill-concealed anxiety.

* * *

Are we now advertising through the London Transport Executive, or did I dream this (with apologies to *Punch*) in the Tube last night?

Are you thin? Are you fat?—Are your arches all flat?
Does your tummy sag down to your knees?
Has your jaw ever locked? Are your sinuses blocked?
Do you cough, do you sniff, do you sneeze?
Have you neurotic pains—or bad varicose veins?
Has your pulmonary valve sprung a leak?
Do you suffer from fits? Are your nerves all to bits?
Try a page of *The Lancet* each week.

As long as the present system of teaching by specialties (however modified by psychiatricosocial projects) continues there is always a certain implication that the GPs are the specialists' throw outs—the boys who could not make the grade in the higher examinations. I feel that there is only one satisfactory solution to the problem of how to make a GP successfully—let GPs of experience train him. Let this be the mainstay of his training, and let the specialties be the titbits thrown in—not the other way round. Thereby the student may learn early in his career the amazing things that can be done with no other apparatus than a stethoscope and a book of prescriptions, and Cinderella may at last have a chance of her date with Prince Charming.

It is surely good that the idea of "trainee assistants" has begun to creep abroad. Why not "trainee students" as well? This would be of mutual benefit, for it would give the GP the chance of one of the things whose lack holds him back most of all—discussion of his patients with a second person.

What a long trail lies before the future GP. After 1952, he must learn physics and chemistry and forget them, learn anatomy and physiology and forget them, learn the specialties and forget most of them, learn something useful as an intern, and serve in the Forces and forget everything, by which time he is eligible to become a trainee assistant.

Manchester

KENNETH D HOPKIRK

TRANSVESICAL PROSTATECTOMY

SIR,—The technique of transvesical prostatectomy described by Mr Crawford Stanley in your issue of Aug 5 is very similar to my own, and I have found this very successful.

I can endorse everything Mr Stanley says about this simple approach. The operation, as he claims, can be easily performed without any special instruments, and the surgeon can easily attend to any associated pathological condition in the cavity of the bladder.

My technique differs somewhat from that of Mr Stanley.

In the first place, I prefer to put my patients on a course of streptomycin for three days before operation, and to continue this for a similar period postoperatively.

The approach is by a transverse suprapubic incision, which gives a satisfactory exposure of the bladder and prostate. The prostate is enucleated as in a Freyer's operation, and when this is done two haemostatic catgut sutures are inserted into the prostatic capsule in its posterolateral aspect, one on each side of the midline, by means of a Boomerang needle, which takes a good bite of the capsule though an ordinary curved needle can be quite satisfactory. This is done to control the main blood vessels to the capsule of the prostate which come from the inferior vesical artery and pass through the capsule into the gland in the posterolateral region in front of the seminal vesicles at the level of the bladder neck. Sometimes, if the bleeding is excessive it is necessary to put in an extra stitch lateral to the two stitches described above. Despite these stitches, oozing continues from the prostatic capsule, and to control this I employ pressure by means of a Foley catheter enveloped in gelatin sponge. This substance which is eventually absorbed, adequately controls venous oozing and I have not so far encountered any mishap following its use. It has been my experience that when the catheter is removed seven days after operation, absorption of the gelatin sponge appears to be complete. In my opinion it does not seem to promote sepsis and the urine is free of bloodstaining within 36–48 hours.

I agree with Mr Stanley that it is essential to perform a vasotomy in every case. In one case in which I omitted this the patient developed epididymitis although he was a youngish subject (56 years old) and his urine was sterile.

Mr Stanley goes on to say that the success of this treatment cannot lie in the operation itself but rather in the use of chemotherapy and antibiotics which enable

closed operations on the bladder to be widely practised. In my opinion, there is no doubt whatever that it is true. The main complications of prostatectomy are (1) shock, (2) sepsis, and (3) hæmorrhage. We now know how to deal adequately with shock, and with the antibiotics (especially streptomycin) we can control sepsis. Hæmorrhage is, in my view, the main remaining danger, and in the technique described above I have found a method for controlling this which I regard as more satisfactory than any other I have used.

I shall hope to report further on this subject when I have used this technique on a larger number of patients.

My thanks are due to Messrs Allen & Hanburys, who kindly prepared the sheets of gelatin sponge used in my preliminary trial.

London W 1

MAURICE LEE

FIRE

SIR,—I have read with much interest your annotation of Aug 12, and Dr Colebrook's letter in your issue of Aug 19.

I wish to add to your list of countries which insist on rigorous tests and inspections of electric fire guards. Australia has an Association of Standards which enforces tests on every proposed design of guard. An inspection gauge or "finger" which looks like a fountain pen, is employed, and this must not be able to touch any "live" parts. In Canada the tests on guards are even more severe. A test finger as well as other limitations are used. For instance, cloth wrapped around the fire guard or placed under the fire, which is laid face down over the cloth, must never scorch even after ten hours. In fact, these Canadian requirements are so numerous that no electric fire with a glowing heat source visible to the user can, to the best of my knowledge, be exported to Canada. Needless to say, these regulations have all the power of law in these countries.

I fully agree with your and Dr Colebrook's remarks about the delay in the appearance of a British standard on electric fires. Such a document (BS 1670/1950) has now been published, but I have not yet seen it. These regulations cannot have the same significance as those in the countries I have mentioned, because they only *advise*, they cannot *compel*. The British Standards Institution can do only what it is asked to do by the manufacturers, it cannot control the standard of equipment by itself. Dr Colebrook's suggestion of an independent technical body for the purpose is a good one, since it would sweep aside any tendency to favour one manufacturer to the detriment of standards. The enforcement of such standards by law is most desirable, this has been done by most countries with only good results. As Dr Colebrook has said, it costs much less to achieve greater safety than to repair the damage caused by its absence.

Bradford.

T J WYNN

SIGNIFICANCE OF COLOURED LINEÆ DISTENSÆ

SIR,—In your issue of June 24 (p 1174) Dr Medvei has quoted from an article by me¹ in which I referred to the observation of Sprague and colleagues² at the Mayo Clinic as to the appearance of red or purple lineæ distensæ during therapy with 'Cortisone,' and my conclusion from this, and from Cushing's syndrome, that where red or purple lineæ distensæ are found clinically one can conclude with reasonable confidence that there is hypersecretion of adrenal cortex hormones (cortisone or steroids of similar chemical constitution). I have considered this further³ and shall be discussing the problem (including the syndrome of adipose gynandrisms)

¹ Simpson S L. *Post-grad med J* 1950 26 201

² Sprague R G, Power M. H., Mason H. L., Albert A., Mathieson D. R., Hench P. S., Kendall E. C., Slocumb C. H., Polley H. F. *Arch intern Med* 1950 85 199

³ Simpson S L. *Post-grad med J* 1950 26 417

cigarette smoking and bronchial carcinoma, may be significant, and are likely to be confirmed when the carcinogens of tobacco smoke from cigarettes have been further studied. These may be 3, 4-benzpyrene from the tobacco tar, and arsenic from the plant spraying.

Professor Dungall's conclusions on the lack of any relation between tarring of roads and bronchial carcinoma may be relevant for Reykjavik, but it would be unwise to dismiss this possible source in other towns. The possible carcinogenicity of tarred roads might well depend on the source of the tar. It is well known that the 3, 4-benzpyrene content of tar depends on its origin and processing. Thus British and Belgian tars have a high content, as have tars derived from high temperature distillation and those obtained from gas works. A relatively low benzpyrene content is found in French and American tars, those obtained from low temperature distillation, and those in bitumen and asphalt.¹ It would be interesting, and possibly instructive, to determine the carcinogen content of the tar used on the roads of Reykjavik and on those of other towns, together with the volume of traffic which is likely to throw tar particles into the atmosphere.

Dulwich Hospital
London S E 22

BERNARD FREEDMAN

SIR,—Clinicians and pathologists are much concerned about the apparent increase in the incidence of cancer of the lung in this and other countries. It is not mere chance that in the week (Aug. 12) when your leading article on tobacco and lung cancer appeared the *British Medical Journal* published a letter on similar lines by Dr E. M. Brookbank. Both admit that, in spite of the considerable amount of work done on the subject in the last twenty years, we are still far from certain that the increase is real or that the conditions in which we live are related to the cause of the disease.

Is not this the time for a small body of active people interested in lung cancer to pool their ideas and plan an investigation which might at some future date provide the facts needed to answer these questions? At present there is no organisation for collecting the crucial data either from the victims of the disease or from the people who might serve as controls.

EDUCATION FOR GENERAL PRACTICE

SIR,—Dr Dicks's article is most lucidly expressed and most stimulating. To find it flanked by articles showing ways in which his holistic conception can be approached, and is being approached, makes your issue of Aug. 26 the most interesting for a long time.

There are one or two points not treated in the neighbouring papers, however, because none of those papers is from a general practitioner. Although I am entirely convinced that Dr Dicks is right in thinking that there has been some breakdown in morale, it is probably unfair to treat financial anxiety as *only* a rationalisation. Mr Bevan was quite right in saying that the majority of general practitioners were up to their eyes in debt for the first fifteen or twenty years that they were in practice—a period quite long enough for an attitude of mind to become ingrained.

Again, there is an answer to the question "What has the community done to decry, depreciate, and demoralise" the general practitioner, considered as "adviser and counsellor in matters often far removed from what is taught in hospitals but close to human health and happiness"? Indeed, there are three answers. Dr Dicks himself is better qualified to say what element of mob psychology created an avid public for Dr Cronin's

The Citadel. I will only point out to him that in addition to a number of doctors who were charlatans there was a public eager, for its own psychological ends, to believe they were all charlatans. The other side of the same penny is a worship of experts by the pseudoscientific inhabitants of a scientific age. The third answer is that over the last twelve years we have been unable to do our proper job for lack of time. When I was first in general practice, and people brought to me family problems that fifty years earlier they would have taken to the vicar, I had the time to do my best with them. During the war I could not do it. There were too many patients per doctor, too many hours of blackout, too many forms to fill in for the Civil Service, too many difficulties in my own living.

Now, however, enough of these troubles have been removed for "holistic medicine" to be again possible. I have proved that local authorities can take the children away from the G.P. only if he is willing. If he holds his own antenatal and infant welfare sessions in his own practice, the mothers will come to him for preference, because of their desire for personal continuity in the treatment and advice they receive. They too have holistic ideas. The job analysis of general practice which Dr Dicks thinks urgent would, I am sure, reveal that the "family doctor" conception endures among the general public, however much the specialist and the bureaucrat may advocate piecemeal methods.

As to the teaching of general practice by general practitioners, which Dr Dicks thinks would have obvious advantages, it was interesting to see in the same issue that at Sheffield every student is to serve a fortnight with a G.P. doing morning surgery and the daily round.

In this area, arrangements are made by which students on the "children's post" can visit certain general practitioners to see how their children's work is arranged, but as the students attend and the practitioners demonstrate voluntarily, students can still complete their training without coming into contact with a G.P.

Perhaps the thing that shows best how much job analysis would reveal as within the sphere of general practice is the successful formation of a mothers' club, based on the special baby sessions in my practice. Its membership is nearly 70% of the possible. It is self-financing, self-serving, and self-organising. It offers no inducements "on the side" but exists solely to provide a forum for discussion of the health of mothers and babies from the point of view of maintenance and prophylaxis. And it flourishes. It has even produced a child in the shape of a fathers' club, which, though much smaller, discusses with animation various conceptions of the ends and methods of education in that broad sense in which "upbringing" is the major part of it.

Collings might not approve of my clock face baumanometer (wrapped in a khaki cloth with red flannel edgings and tied round with string), whose age I cannot tell since my deceased partner gave it to me when he was over seventy. But if Dr Dicks will give me his blessing, I shall not mind.

York

F. CHARLOTTE NAISH

SIR,—Having read Dr Dicks's excellent article of Aug. 26, one feels that, unlike many other non-G.P. writers on the same subject, he has got around to the key point.

It is generally recognised that if one is going to become, say, a cardiologist, one does not get a deep sea diver to teach one the job. Similarly we have not yet heard of the urogenital surgeon who learned his trade from an electrical engineer. Yet although it is agreed that general practice and hospital specialist practice are, in the main, two distinct and non-overlapping fields, this lesson has not yet got generally home.

As long as the present system of teaching by specialties (however modified by psychiatricosocial projects) continues there is always a certain implication that the G.P.s are the specialists' throw-outs—the boys who could not make the grade in the higher examinations. I feel that there is only one satisfactory solution to the problem of how to make a G.P. successfully—let G.P.s of experience train him. Let this be the mainstay of his training, and let the specialties be the titbits thrown in—not the other way round. Thereby the student may learn early in his career the amazing things that can be done with no other apparatus than a stethoscope and a book of prescriptions, and Cinderella may at last have a chance of her date with Prince Charming.

It is surely good that the idea of "trainee assistants" has begun to creep abroad. Why not "trainee students" as well? This would be of mutual benefit, for it would give the G.P. the chance of one of the things whose lack holds him back most of all—discussion of his patients with a second person.

What a long trail lies before the future G.P. After 1952, he must learn physics and chemistry and forget them, learn anatomy and physiology and forget them, learn the specialties and forget most of them, learn something useful as an intern, and serve in the Forces and forget everything, by which time he is eligible to become a trainee assistant.

Manchester

KENNETH D. HOPKIRK

TRANSVESICAL PROSTATECTOMY

SIR,—The technique of transvesical prostatectomy described by Mr Crawford Stanley in your issue of Aug 5 is very similar to my own, and I have found this very successful.

I can endorse everything Mr Stanley says about this simple approach. The operation, as he claims, can be easily performed without any special instruments, and the surgeon can easily attend to any associated pathological condition in the cavity of the bladder.

My technique differs somewhat from that of Mr Stanley.

In the first place I prefer to put my patients on a course of streptomycin for three days before operation and to continue this for a similar period postoperatively.

The approach is by a transverse suprapubic incision, which gives a satisfactory exposure of the bladder and prostate. The prostate is enucleated as in a Freyer's operation, and when this is done two hæmostatic catgut sutures are inserted into the prostatic capsule in its posterolateral aspect, one on each side of the midline, by means of a Boomerang needle, which takes a good bite of the capsule though an ordinary curved needle can be quite satisfactory. This is done to control the main blood vessels to the capsule of the prostate which come from the inferior vesical artery and pass through the capsule into the gland in the posterolateral region in front of the seminal vesicles at the level of the bladder neck. Sometimes, if the bleeding is excessive it is necessary to put in an extra stitch lateral to the two stitches described above. Despite these stitches oozing continues from the prostatic capsule and to control this I employ pressure by means of a Foley catheter enveloped in gelatin sponge. This substance, which is eventually absorbed adequately controls venous oozing and I have not so far encountered any mishap following its use. It has been my experience that when the catheter is removed seven days after operation absorption of the gelatin sponge appears to be complete. In my opinion, it does not seem to promote sepsis, and the urine is free of bloodstaining within 36–48 hours.

I agree with Mr Stanley that it is essential to perform a vasotomy in every case. In one case in which I omitted this the patient developed epididymitis although he was a youngish subject (56 years old) and his urine was sterile.

Mr Stanley goes on to say that the success of this treatment cannot lie in the operation itself but rather in the use of chemotherapy and antibiotics which enable

closed operations on the bladder to be widely practised. In my opinion, there is no doubt whatever that it is true. The main complications of prostatectomy are (1) shock, (2) sepsis, and (3) hæmorrhage. We now know how to deal adequately with shock, and with the antibiotics (especially streptomycin) we can control sepsis. Hæmorrhage is, in my view, the main remaining danger, and in the technique described above I have found a method for controlling this which I regard as more satisfactory than any other I have used.

I shall hope to report further on this subject when I have used this technique on a larger number of patients.

My thanks are due to Messrs Allen & Hanburys, who kindly prepared the sheets of gelatin sponge used in my preliminary trial.

London W 1

MAURICE LEE

FIRE

SIR,—I have read with much interest your annotation of Aug 12, and Dr Colebrook's letter in your issue of Aug 19.

I wish to add to your list of countries which insist on rigorous tests and inspections of electric fire guards. Australia has an Association of Standards which enforces tests on every proposed design of guard. An inspection gauge or "finger," which looks like a fountain pen, is employed, and this must not be able to touch any "live" parts. In Canada the tests on guards are even more severe. A test finger as well as other limitations are used. For instance, cloth wrapped around the fire-guard or placed under the fire, which is laid face down over the cloth, must never scorch even after ten hours. In fact, these Canadian requirements are so numerous that no electric fire with a glowing heat source visible to the user can, to the best of my knowledge, be exported to Canada. Needless to say, these regulations have all the power of law in these countries.

I fully agree with your and Dr Colebrook's remarks about the delay in the appearance of a British standard on electric fires. Such a document (as 1670/1950) has now been published, but I have not yet seen it. These regulations cannot have the same significance as those in the countries I have mentioned, because they only *advise*, they cannot *compel*. The British Standards Institution can do only what it is asked to do by the manufacturers, it cannot control the standard of equipment by itself. Dr Colebrook's suggestion of an independent technical body for the purpose is a good one, since it would sweep aside any tendency to favour one manufacturer to the detriment of standards. The enforcement of such standards by law is most desirable, this has been done by most countries with only good results. As Dr Colebrook has said, it costs much less to achieve greater safety than to repair the damage caused by its absence.

Bradford.

SIGNIFICANCE OF COLOURED LINEÆ DISTENSÆ

SIR,—In your issue of June 24 (p 1174) Dr Vedvei has quoted from an article by me¹ in which I referred to the observation of Sprague and colleagues² at the Mayo Clinic as to the appearance of red or purple lineæ distensæ during therapy with 'Cortisone,' and my conclusion from this and from Cushing's syndrome that where red or purple lineæ distensæ are found clinically one can conclude with reasonable confidence that there is hypersecretion of adrenal cortex hormones (cortisone or steroids of similar chemical constitution). I have considered this further,³ and shall be discussing the problem (including the syndrome of adipose gynandrisms)

cigarette smoking and bronchial carcinoma, may be significant, and are likely to be confirmed when the carcinogens of tobacco smoke from cigarettes have been further studied. These may be 3, 4-benzpyrene from the tobacco tar, and arsenic from the plant spraying.

Professor Dungl's conclusions on the lack of any relation between tarring of roads and bronchial carcinoma may be relevant for Reykjavik, but it would be unwise to dismiss this possible source in other towns. The possible carcinogenicity of tarred roads might well depend on the source of the tar. It is well known that the 3, 4-benzpyrene content of tar depends on its origin and processing. Thus British and Belgian tars have a high content, as have tars derived from high temperature distillation and those obtained from gas works. A relatively low benzpyrene content is found in French and American tars, those obtained from low temperature distillation, and those in bitumen and asphalt.¹ It would be interesting, and possibly instructive, to determine the carcinogen content of the tar used on the roads of Reykjavik and on those of other towns, together with the volume of traffic which is likely to throw tar particles into the atmosphere.

York

F. CHARLOTTE NASH

SIR,—Having read Dr Dicks's excellent article of Aug. 26, one feels that, unlike many other non-G.P. writers on the same subject, he has got around to the key point.

It is generally recognised that if one is going to become, say, a cardiologist, one does not get a deep sea diver to teach one the job. Similarly we have not yet heard of the urogenital surgeon who learned his trade from an electrical engineer. Yet although it is agreed that general practice and hospital specialist practice are, in the main, two distinct and non-overlapping fields, this lesson has not yet got generally home.

it is important that the medical staff of departments of pathology selected for teaching, in hospitals other than teaching hospitals, should be adequate to allow the senior members time in which to teach all juniors systematically. Such an arrangement would, in the end, more than justify the expense of the salaries paid out for little immediate return other than, say, resident alternate might duty required of trainees.

When, in the future, conditions become more stabilised it should be possible for the university departments of pathology to be responsible for the initial period of post graduate training and provide, in a two year course, a curriculum similar to that at present followed for one year at the Postgraduate Medical School of London for the university diploma in clinical pathology. The additional year would permit of methods being learned less hurriedly and practised more frequently, and at the same time allow of related systematic reading. Such university postgraduate courses in pathology for all trainees should not be regarded as the ideal and the unattainable, but rather as the best and an essentially economic means of providing well trained pathologists.

J F HEGGIE

North Middlesex Hospital London N 18

PAY OF THE PSYCHIATRIC SOCIAL WORKER

SIR,—In your issue of Aug 12, Dr Sessions Hodge describes an advertisement issued by Nottinghamshire county council public health department as "a demigration of the professional standards" of psychiatric social workers. I would suggest that, far from affronting that profession, this county council have done it a service by calling attention to its plight.

Nottinghamshire offered £370-£20 p.a.-£530 p.a. to duly qualified psychiatric social workers, and to "unqualified persons"—that is, social workers without the mental health certificate—£480-£15 p.a.-£525—that is to say, the duly authorised officer scale.

Thus it seems that the psychiatric social worker is not only inadequately paid but is penalised to the tune of £110 p.a. for holding an additional qualification for which he or she has been selected on merit and trained for an additional year. The gross difference is, of course, in the starting salary. The scale for psychiatric social workers was last revised in December, 1946, since when the cost of living has risen by 13 points. That it has not been revised since then is not for want of trying.

There are now between 80 and 100 vacant posts awaiting qualified psychiatric social workers. Further, the number of applicants selected for training does not wholly fill even existing courses, and those who do the selection are concerned that not enough applicants of the right quality are coming forward for this very responsible work. Their value is unquestioned, I for one recognise how greatly my own professional contribution depends on that of my psychiatric social worker colleagues.

The present salary-scale, agreed between the voluntary hospitals and the medical auxiliaries before the National Health Service started, has been the subject of negotiation through the Whitley Council, and, as your annotation suggests, they have been "unaccountably slow in reaching agreement." To block negotiations by procrastination is to cease to negotiate. If there is no intention to move, then it is difficult to see what other course can be taken except to strike. But professional people are neither accustomed nor willing, so far, to use the strike as a weapon, and any profession concerned with human welfare and suffering would be loth to withdraw its services in order to force revision of salary-claims, however well this action was justified. To be penalised by £110 a year for holding a higher qualification is so patently absurd that in industry it would be met by a threat to strike which would command so much public

interest and sympathy that probably the strike would never be necessary. In the negotiations which preceded the Appointed Day, the risk that the unwillingness of professional people to strike would be exploited was indignantly repudiated.

London W 1

E M CREAK

SIR,—On behalf of the Association of Psychiatric Social Workers I would like to thank you for the consideration you have given to the situation facing our members. Apart from the deterrent effect of the present low salary scales on recruitment, to which you and Dr Sessions Hodge refer, there is a very real threat to the professional status of psychiatric social workers. Some employing bodies, disregarding the high standard of our professional training, seem to take the view that years of experience in the administration of the Mental Deficiency and Mental Treatment Acts are equivalent to training as a psychiatric social worker. On the other hand, there is evidence in other quarters that understanding and appreciation of psychiatric social work has been growing apace—much faster than the present supply of personnel, for there are some 80-100 vacant posts. The Nottingham council is by no means the only employing authority faced by the twin evils of a shortage of the trained personnel whom they would wish to employ, and a regulation obliging them to offer a higher salary to less well qualified workers whom they might wish to employ only temporarily. The present situation is caught in an administrative tangle, so that the less adequately trained workers in the mental health field have received better treatment in negotiation than ourselves. In this situation good will has proved insufficient.

A full statement of our case has been made by our representatives on the Whitley Council, and in addition the association has repeatedly submitted memoranda on the professional duties and responsibilities of psychiatric social workers to the Mackintosh Committee, the Ministry of Health, and employing bodies. These representations are quite ineffective in face of the present administrative regulation which binds officials in the National Health Service. Our only hope now is for a professional and informed public opinion which will act on our behalf. We do not press for undue financial advantage in face of the national economic situation, but only for some equitable settlement, so that psychiatric social work may continue to develop its proved values in the mental health field.

H E HOWARTH

Chairman Association of
Psychiatric Social Workers

ESTIMATION OF PROTHROMBIN-TIME

SIR,—In his letter of July 29 Prof A. L. Copley (to whom I am most grateful for his distinguished support) confirmed the observation reported in my letter of June 17—that prothrombin time estimations are made irregularly by traces of soapless detergents. I have also received letters from laboratory workers in this country and abroad confirming my observation, and some of them tell me that they have been aware of the effect by trial and error for several years. Others thank me for pointing out a fact which may explain why they have had difficulty with prothrombin time estimations. All this shows how important it is that technical details of this type should be published at the first opportunity. From the letters I have received, it is clear that at various places in the world a good deal of time and patience have been spent in making the same observation all over again, and in some places where the problem had not been solved prothrombin time estimation has been unreliable and irksome.

Pathological Laboratory,

Pembury Kent.

H LEHMANN

and asking for criticisms at the January meeting of the endocrine section of the Royal Society of Medicine.

I would, however, briefly comment on Dr Medver's reference to the absence of such coloured striæ in some cases of Cushing's syndrome and their presence in a "normal" young man he briefly describes. I would certainly agree with the former as a matter of fact, and have recently had such a case in which an adrenal tumour was removed. However, the patient was not really adipose although the limbs had become thinner and the trunk a little fatter. I should be somewhat disquieted if lincæ distensæ were present in a case of Cushing's syndrome but were white rather than red or purple, especially if plethora and reddish countenance were present, with or without polycythæmia. One would not doubt the diabetogenic potentialities of the adrenal 11 oxysteroids because diabetes was not present in every case of Cushing's syndrome. Another condition in which red or purple lincæ distensæ develop is pregnancy—one of the physiological states in which the active phase of rheumatoid arthritis (as observed by Hench) may be temporarily abolished and in which adrenal cortical steroids of the cortisone type are excreted in excess. Such lincæ remain after pregnancy, but lose their colour. As to the second point, I think Selye would be interested in the development of purple lincæ distensæ during an infection but puzzled by their persistence as coloured lincæ for some years in the absence of an endocrinopathy. So am I, but there are, in my view, a number of clinical endocrinopathies not yet elucidated or even described, and I have always taken the view that there are few, if any, endocrinopathies that have not parallel minor indications in "normal" or intermediate states. In fact, one of the rewards of the elucidation of major endocrinopathies is the light thrown on the physiology of the endocrine glands. In spite of the above considerations, however, I do not regard my views on the significance of coloured lincæ distensæ, as yet, as being substantiated histologically or by hormone assay.

London, W 1

S LEONARD SIMPSON

"WEYBRIDGE P P D TUBERCULIN"

SIR,—A footnote to Smith and Vollum's paper of Aug. 19, on the Effects of Intrathecal Tuberculin and Streptomycin in Tuberculous Meningitis, states that the purified protein derivative used was the standard preparation supplied by this laboratory. Since then we have received numerous requests from hospitals for supplies, and it may save correspondence and telephone queries (either to myself or to Mr Paterson, who is in charge of production) if I make the following points clear.

1 The method of preparation of Weybridge P P D tuberculin is described in my article in the *Veterinary Journal* (1946, 102, 267). (There is a printer's error—subsequently corrected—on p. 273 where P A I tuberculin was given as 0.22–0.28 mg protein per ml instead of 2.2–2.8 mg.)

2 Purified protein derivatives (P P D) from various acid-fast organisms are stocked in dry powder form at Weybridge for research purposes and for use as standards, but for routine purposes neutral solutions are issued at various specified strengths in M/15 phosphate buffer containing 10% glycerol and 0.5% phenol. The Weybridge P P D dry powder made from human strain *Mycobacterium tuberculosis* has been tested against Dr Florence Seiberts' limited stock of "pioneer material," on guinea-pigs sensitised to human strain. Potencies are the same, so any medical practitioner who has used her American material for the Mantoux test can compare results with any obtained with Weybridge material on the basis of equivalent weights of P P D.

3 The solution used by Smith and Vollum contained 1.5 mg P P D per ml. This strength is approximately equivalent in potency to the "international standard" held at Hampstead, against which commercial firms standardise their O T by guinea-pig tests. In my original article I gave the potency equivalent of the Hampstead material as 2 mg Weybridge

P P D per ml, but subsequent tests have shown 1.5 mg to be rather closer. Hence if it is desired to use the same material for the intradermal Mantoux test as for intrathecal injection, dilutions can be based on the assumption that the 1.5 mg per ml solution is equivalent to O T.

4 The "standard" solution of P P D mentioned by Smith and Vollum as containing 7.5 microgrammes per ml, to be diluted further 10 fold, 100 fold, or 1000 fold, is obviously made by diluting the original solution (1.5 mg or 1500 µg per ml) 200 fold—presumably with sterile saline.

5 At such dilutions a single millilitre phial goes a long way. Hence when a request comes through without mention of quantity required, a single phial is automatically despatched as a "complimentary issue for experimental purposes without charge." More is sent if needed.

Since current production of human strain P P D at Weybridge would, if all were issued at 1.5 mg per ml (O T potency), amount to over a million millilitres per annum, it is not worth the administrative cost of collecting odd shillings from medical practitioners still at the experimental stage in using P P D. The charge to veterinary practitioners is a shilling per millilitre (arbitrarily fixed at the price charged by commercial firms for O T), but for the intradermal test in cattle the material is used neat—not diluted 1000–10,000 times as it would be for the Mantoux intradermal test in the human subject. Most of the large output at Weybridge is not actually sold but issued for use by the Ministry's own inspectorate staff in official testing—for the "comparative test," using both mammalian and avian tuberculin, as indicated in my letter to the *British Medical Journal* (1946, 1, 812).

(Ministry of Agriculture and Fisheries), Weybridge

THE PATHOLOGIST'S TRAINING

SIR,—It was with considerable interest that I read of the recommendations of the committee set up by the Royal College of Physicians "to inquire into the training and recognition of medical specialists in pathology, and to make recommendations concerning this branch of medical practice in the future." Having been actively engaged in the teaching of pathology for almost twenty years I write to point out a condition which should apply to all pathologists in training.

I consider it imperative that the fundamental principles of pathology should be assimilated and inculcated correctly, systematically, and thoroughly from the very outset, and not be left, as is implied in your annotation (Aug. 26) on the report, until the third, fourth, or fifth year when the trainee is in a university or associated department and free from routine responsibilities. As a consequence, the recommended generous provision of posts in hospital laboratories, and in the departments of clinical pathology of universities and teaching hospitals, must be such as to permit candidates specially selected for training to be free or relatively free from routine responsibilities in the first, or first and second, years of training. This would enable all trainees systematically to acquire within two years considerable competence and experience of laboratory methods in each of the four divisions of pathology, and at the same time to make some study of the four subjects in selected and supervised reading. By this means candidates would receive a good grounding in pathology and be the better able to profit from the three succeeding years, in which a selected subject or one of special interest could form the basis of individual investigation and study suitable for presentation as the thesis for a higher degree.

This is emphasised because, unless first and second year trainees are appointed *supernumerary* to departmental establishments in hospital laboratories selected for training, those in training would be employed mainly or wholly in repetitive routine work and would learn little of the fundamentals of their subject and perhaps only a limited repertoire of technical methods. As a corollary,

it is important that the medical staff of departments of pathology selected for teaching, in hospitals other than teaching hospitals, should be adequate to allow the senior members time in which to teach all juniors systematically. Such an arrangement would, in the end, more than justify the expense of the salaries paid out for little immediate return other than, say, resident alternate night duty required of trainees.

When, in the future, conditions become more stabilised it should be possible for the university departments of pathology to be responsible for the initial period of post-graduate training and provide, in a two year course, a curriculum similar to that at present followed for one year at the Postgraduate Medical School of London for the university diploma in clinical pathology. The additional year would permit of methods being learned less hurriedly and practised more frequently, and at the same time allow of related systematic reading. Such university postgraduate courses in pathology for all trainees should not be regarded as the ideal and the unattainable, but rather as the best and an essentially economic means of providing well trained pathologists.

J F HEGGIE

PAY OF THE PSYCHIATRIC SOCIAL WORKER

SIR—In your issue of Aug 12, Dr Sessions Hodge describes an advertisement issued by Nottinghamshire county council public health department as "a denigration of the professional standards" of psychiatric social workers. I would suggest that, far from affronting that profession, this county council have done it a service by calling attention to its plight.

Nottinghamshire offered £370-£20 p.a.-£530 p.a. to duly qualified psychiatric social workers, and to "unqualified persons"—that is social workers without the mental health certificate—£180-£15 p.a.-£525—that is to say, the duly authorised officer scale.

Thus it seems that the psychiatric social worker is not only inadequately paid but is penalised to the tune of £110 p.a. for holding an additional qualification for which he or she has been selected on merit and trained for an additional year. The gross difference is, of course, in the starting salary. The scale for psychiatric social workers was last revised in December, 1946, since when the cost of living has risen by 13 points. That it has not been revised since then is not for want of trying.

There are now between 80 and 100 vacant posts awaiting qualified psychiatric social workers. Further, the number of applicants selected for training does not wholly fill even existing courses, and those who do the selection are concerned that not enough applicants of the right quality are coming forward for this very responsible work. Their value is unquestioned, I for one recognise how greatly my own professional contribution depends on that of my psychiatric social worker colleagues.

The present salary scale, agreed between the voluntary hospitals and the medical auxiliaries before the National Health Service started, has been the subject of negotiation through the Whitley Council and, as your annotation suggests, they have been "unaccountably slow in reaching agreement." To block negotiations by procrastination is to cease to negotiate. If there is no intention to move, then it is difficult to see what other course can be taken except to strike. But professional people are neither accustomed nor willing, so far, to use the strike as a weapon, and any profession concerned with human welfare and suffering would be loth to withdraw its services in order to force revision of salary-claims however well this action was justified. To be penalised by £110 a year for holding a higher qualification is so patently absurd that in industry it would be met by a threat to strike which would command so much public

interest and sympathy that probably the strike would never be necessary. In the negotiations which preceded the Appointed Day, the risk that the unwillingness of professional people to strike would be exploited was indignantly repudiated.

London W 1

E M CREAK

SIR,—On behalf of the Association of Psychiatric Social Workers I would like to thank you for the consideration you have given to the situation facing our members. Apart from the deterrent effect of the present low salary scales on recruitment, to which you and Dr Sessions Hodge refer, there is a very real threat to the professional status of psychiatric social workers. Some employing bodies, disregarding the high standard of our professional training, seem to take the view that years of experience in the administration of the Mental Deficiency and Mental Treatment Acts are equivalent to training as a psychiatric social worker. On the other hand, there is evidence in other quarters that understanding and appreciation of psychiatric social work has been growing apace—much faster than the present supply of personnel, for there are some 80-100 vacant posts. The Nottingham council is by no means the only employing authority faced by the twin evils of a shortage of the trained personnel whom they would wish to employ, and a regulation obliging them to offer a higher salary to less well qualified workers whom they might wish to employ only temporarily. The present situation is caught in an administrative tangle, so that the less adequately trained workers in the mental health field have received better treatment in negotiation than ourselves. In this situation good will has proved insufficient.

A full statement of our case has been made by our representatives on the Whitley Council, and in addition the association has repeatedly submitted memoranda on the professional duties and responsibilities of psychiatric social workers to the Mackintosh Committee, the Ministry of Health, and employing bodies. These representations are quite ineffective in face of the present administrative regulation which binds officials in the National Health Service. Our only hope now is for a professional and informed public opinion which will act on our behalf. We do not press for undue financial advantage in face of the national economic situation, but only for some equitable settlement, so that psychiatric social work may continue to develop its proved values in the mental health field.

ESTIMATION OF PROTHROMBIN-TIME

SIR,—In his letter of July 29 Prof A L Copley (to whom I am most grateful for his distinguished support) confirmed the observation reported in my letter of June 17—that prothrombin time estimations are made irregular by traces of soapless detergents. I have also received letters from laboratory workers in this country and abroad confirming my observation, and some of them tell me that they have been aware of the effect by trial and error for several years. Others thank me for pointing out a fact which may explain why they have had difficulty with prothrombin-time estimations. All this shows how important it is that technical details of this type should be published at the first opportunity. From the letters I have received, it is clear that at various places in the world a good deal of time and patience have been spent in making the same observation all over again, and in some places where the problem had not been solved prothrombin time estimation has been unreliable and irksome.

PUBLICITY FOR CANCER

SIR,—Your annotation last week refers to my article of Sept. 9 in the *Medical Officer*. I am convinced that thousands of lives would be saved if correct methods of cancer education and publicity were carried out on a large scale, because the better knowledge concerning symptoms would enable patients to seek medical advice at a stage in the disease when it may be curable. On the other hand, I agree with you that it is unfortunate that the first big publicity given to the disease should take the form it did in *Picture Post*. It will, I fear, strengthen the hands of those members of the medical profession who, not having given the matter sufficient consideration, oppose the education of the public concerning cancer.

London W 1

MALCOLM DONALDSON

PUERPERAL URÆMIA DUE TO ACUTE UPPER-NEPHRON NEPHROSIS

SIR,—Dr Bull and Dr Lennox raise an interesting point in their letter of Aug. 19. The possibility of sucrose activity had occurred to us. Owing to the frequent use of that substance in this hospital in the past, we were able to examine material from several fatal cases in which large amounts had been given. The renal changes were not at all like those described by us in our paper on post partum uræmia.

Perhaps, however, it would be better to confine discussion to our case no. 1. This patient died of uræmia after 13 days' illness. The only gross change in the kidneys was hydropic degeneration—really necrosis—of first convoluted tubules. At no time did she receive sucrose. Intravenous glucose was administered on one occasion only, 11 days before her death. It seems unlikely that this could be responsible for the appearances noted post mortem. Assuming, however, that our interpretation is wrong and that the histological changes were merely due to glucose, at least two questions arise. Why did the patient suffer from oliguria, and what was the cause of her uræmia? One shudders to think of the fate of all those patients who, in the course of tubular reabsorption tests, receive large amounts of glucose in concentrated solution.

With regard to Mr Bracey's thesis (Sept. 2), we would not disagree with the first part which states that the changes described were related to anoxia. The points he raises in the second part are rather difficult to understand. Assuming that overhydration did occur in these patients, why were the lesions localised to the upper part of the nephron while the distal convoluted tubules, which are commonly thought to be the main sites of salt and water interchange, were unaffected? If the lesions in the upper nephron were, in fact, due to overhydration, it is strange that these lesions have not previously been described, since the common treatment of oliguria, until recently, was overhydration. Again, does Mr Bracey consider that overhydration, by producing the lesions in the upper nephron, can cause oliguria?

Royal Maternity and
Women's Hospital GlasgowA D T GOVAN
I MACGILLIVRAY

SIR,—The findings in an experiment carried out by a colleague and myself may perhaps be of interest in relation to the article by Dr Telford Govan and Dr MacGillivray (July 22) and the subsequent correspondence.

The nerves accompanying the left renal artery of an anaesthetised rabbit were stimulated at intervals over a period of about six hours, and the kidneys thereafter removed for fixation and histological examination. Dr G. J. Cunningham found marked changes (not detailed here) in the left kidney, and no corresponding ones in the right kidney. Prof. J. H. Dible, who also examined the left kidney, said "I am struck by what

appears to be a swelling of the primary convoluted tubule cells—intracellular oedema which seems to be the chief factor in the swelling of the organ. A few of the secondary convoluted tubule cells and a good many collecting tubules contain hyaline cast like material."

London W 1

JOHN SOPHIAN

PSYCHOSOMATIC MEDICINE

SIR,—I read with great interest Professor Pickering's article of July 15. As a student I was more fortunate than he was, for, far from being out of sympathy with my teachers' favourite theories, I was often enthused by them. The teacher to whom I am thus indebted most is Professor Pickering himself, and I was the more disappointed to read how lightly he dismisses the psychosomatic concept.

No doubt the apparent rejection of this concept by so many eminent physicians is due to several causes: (1) failure of the psychiatrists concerned to define their ideas clearly, (2) the time lag which makes our conservative (still Virchow dominated) profession the best part of a century and a half out of line with modern philosophy, and (3) unconscious blind spots in surveying the realm of the psyche.

The term "psychosomatic" is bad, for it emphasises the lately united fracture line between mind and body, living (reacting) in a total environment, but the idea that man is a unified totality (of psyche and soma) has been used by medical men certainly before and even since the mechanistic phase in medicine. Indeed, it is with such an idea that we all approach patients. Psychosomatic medicine is in fact the simultaneous study of psychological and somatic factors in their interrelation, in their relation to the whole person, and in the relation of the total personality to the total environment (physical and mental).

I cannot think that Professor Pickering had this concept in mind when he squeezed "psychosomatic origin" between "focal sepsis" and "the diseases of adaptation" and dismissed it in one paragraph. Probably he was concerned rather with the "circumscribed" hypothesis that there are certain diseases which find their origin mainly in emotional conflict. Here the operative words are "origin" and "mainly", for the emotion may be of major (but not total and single) importance at only one stage in the natural history of these diseases. Though some naïve attempts may have been made to demonstrate "a significant association between the abnormal mental states and the diseases in question," few are making such attempts now. Nevertheless there is strong evidence of a relation between disturbed emotion (psychic) and these diseases (somatic)—a relation not necessarily causal but as significant as the relation between electroencephalographic changes and epilepsy or between insulin and diabetes. Again, if it is conceded that "psychotherapy" sometimes (even rarely) "produces dramatic or repeatable effects in these diseases" it is surely necessary to explain that fact instead of rejecting it. The effect of psychotherapy (in centres where it can be judged fairly) is as dramatic and repeatable as the effect of any of the main weapons of therapeutics—which are notoriously capricious because they have to obey psychosomatic as well as pharmacological laws. Professor Pickering says that "the hypothesis fails to account for (a) the variety of mental states causing the same disease entity, and (b) a single mental state being associated with a variety of disease entities", and cast in the above words the statement is undeniable. Yet it is clear that the psychosomatic concept does not seek to account for things in that way, nor is it certain that there is such a thing as a "disease entity". Further, using Professor Pickering's valuable approach to research

through therapy, one has often observed in the psychotherapy of a patient that he runs the gamut of such apparently disconnected "diseases" as early essential hypertension, migraine, asthma, urticaria, frequent colds, and even a frank neurosis, before he returns to a fair adjustment to both the internal and external environment. The effects of adrenocorticotrophic hormone further tend to discredit the idea of "disease entities."

However, it is the final tone of the address which most affected me personally. Though I can see the use of scepticism and caution in medicine, I believe our teachers would give more impetus to fruitful research if they viewed the entire field with the eyes of Dr J S L Brown, of McGill University. He compares it to icebergs, seven-eighths of which are submerged in water (and have hitherto not been perceived by medical science), and he points out that it is only the peaks on the surface that we have been in the habit of calling diseases. To this we should add that icebergs are constantly drifting and changing in shape, and therefore, at best, when we study them we isolate them from the time space continuum.

Department of Psychiatry
University of Toronto

D CAPPON

SIR,—As Dr Halliday (Sept 2) says, the abuse recently heaped on "psychosomatic medicine" derives from its wrongful employment, it is not a description of the no man's land between medical psychology and "pure medicine," but merely a term found useful by the clinician in recent years to emphasise the inseparable alliance between the patient's psyche and its more obvious corporeal attachment.

I do not remember, as a medical student twenty years ago, hearing any emphasis placed on the relation between the patient's mental make up and his symptoms. The disturbance of function which gives rise to a symptom may be purely organic in origin or purely emotional, or (more usually) a mixture of both. The only virtue of the current popular use of the word "psychosomatic" is that it drives home the existence of this last large symptomatic group. Continual awareness of the interplay of mind and body is ever necessary, and is one of the characteristics of the good clinician.

The student should be introduced to the relationship of mind and body at the very outset of his clinical career. It is important that he should realise that anorexia, for example, can be produced by anxiety as well as by cancer of the stomach, for he will certainly see more nervous anorexias than those due to malignant disease. The right teacher to emphasise this is the general physician, and the right moment is the first student week in the wards or the outpatient department.

RONALD ELLIS

Stanley Hospital
Liverpool

Physician
United Liverpool Hospitals

SIR,—Dr Eastwood (Aug 12) would have us draw a clear distinction between primary bodily illness causing psychological disease and primary psychological disease causing bodily illness. It is the essence of the concept of "body mind" that such distinction is impossible. As to the rarity of psychosomatic illness in general practice I should have thought that asthma, duodenal ulcer, and spastic colon were common in general practice and that these diseases were classed as psychosomatic by most authorities.

As to the charge that psychogenic disease is too often diagnosed on the strength of negative laboratory findings, it is hard to see what else a doctor can do when faced with, say a patient who complains of indigestion, when the X ray report is negative and no occult blood is found in the stools. Very likely the doctor will know that the patient's wife is a slut or that he has financial worries

and in any case a tactful history-taking will discover facts like these. Are not such cases also common in general practice?

Bridlington

P D H CHAPMAN

SUBSTITUTES FOR CURARE

SIR,—I read with great interest your leading article on this subject¹ and subsequent correspondence.

I first used *d* tubocurarine chloride in connection with convulsion therapy in August, 1939, and have subsequently had experience with 'Intocostrin,' decamethonium iodide, and 'Flaxedil'. I can corroborate Dr Davies's² observations that the synthetic substances do not affect the vital capacity to anything like the same extent as the alkaloid. Indeed, the difference is very striking when registered graphically. In my experience flaxedil is, however, in turn superior to decamethonium iodide in this and other respects³.

I have also read with great interest your correspondence on neostigmine injections in connection with this treatment. Without disagreeing with the principle of such a routine, I regard it as essential when handling this class of drug that an artificial respirator should always be at hand. In the last ten years I have used one or other of these drugs many hundreds of times, and without this precaution I would very occasionally have felt anxiety for the patient's welfare. At one time psychiatrists did not seem to agree that convulsion therapy merited the routine use of a muscular relaxant, and fracture complications and, indeed, fatalities continue in some clinics where such a routine is not followed.

The administration of either neostigmine or penta methonium iodide is sometimes fraught with hazards, but if one's vigilance is centred on respiration rather than physiological antidotes no anxiety whatever need be entertained. In our experience at this hospital, flaxedil is the muscular relaxant of choice and this is also the opinion of the nursing staff, who are in a good position to estimate the value of the physician's treatment unhampered by prejudice.

HAROLD PALMER

AFTER GASTRECTOMY

SIR,—Your well balanced and informative leading article last week accurately reflects the predominant surgical opinion and so gives scant attention to the anterior Polya type of operation. But I believe this operation to be preferable to all others in its freedom from after effects. Certainly the Billroth I operation does not give such good results, possibly because of the loss of former freedom of movement of the stomach when it distends. The anterior Polya operation is simple. There is no objection to bringing the jejunum up in front of the colon, because if the afferent loop is attached to the greater curvature its passage from the duodeno-jejunal junction to the greater curvature lies in front of the very deeply placed splenic flexure and there is no danger of compressing the transverse colon.

At the completion of the operation the stomach retracts up into the abdomen under the left costal margin, and the line of the anastomosis will be seen to be almost horizontal but often with the greater curvature end a little lower than the other. Skagrams show that the blind end of the duodenum always fills. That food should pass into this part of the bowel is wholly desirable. The duodenal cap, the proper mixing and neutralising chamber for the acid chyme and pancreatic juices, has gone, the blind end serves this purpose. It fills, performs its mixing functions, and then expels its contents onwards along the jejunum. In order that this process should take place easily, it is essential that there should be no

Professor Pickering says that "the hypothesis fails to account for (a) the variety of mental states causing the same disease entity, and (b) a single mental state being associated with a variety of disease entities", and cast in the above words the statement is undeniable. Yet it is clear that the psychosomatic concept does not seek to account for things in that way, nor is it certain that there is such a thing as a "disease entity". Further, using Professor Pickering's valuable approach to research

After the 1914-18 war he was energetic in reviving the Association of Physicians of Great Britain, of which he was successively secretary, treasurer, and president. At the Royal Society of Medicine he had presided over the sections of diseases of children and of medicine, and in 1937 Queen's University, Belfast, conferred on him the honorary degree of LL.D. while he was presiding over the section of diseases of children at the B.M.A. meeting there. The Royal Australasian College of Physicians also made him an honorary fellow.

H. L. T. writes. "Herbert Morley Fletcher had many attributes, physical and intellectual, and throughout a long life he used them to the full for his own enjoyment and for giving pleasure to others. Outside the strict professional paths of hospital and practice he employed his administrative and social gifts in many directions. King Edward's Hospital Fund was an interest very close to him. He served it for over thirty years and less than four months ago he was visiting convalescent homes on its behalf. A good committee man and a good chairman with a grasp of essentials, he had the power of keeping speakers to the point with an easy hand. He never lost his pleasure in athletics from the time when he was president of the C.U.A.C., and he rarely missed the Oxford and Cambridge sports. Indeed he enjoyed all social occasions. An attractive voice and a flow of entertaining conversation made him a delightful companion, and he liked a good cigar and a glass of wine. Friendliness, kindness, courtesy, and a boyish enthusiasm which never flagged, these he offered to fortune, and fortune gave him two long and happy married lives."

Dr. Morley Fletcher's first wife, Ethel Frances Crossley, of Halifax, by whom he had two sons and three daughters, died in 1918. One of his daughters married Mr. H. U. Willink, whose sister Mary Christina Willink, became his second wife. There are two daughters of this marriage.

O. M. H. H. writes. "I met Morley Fletcher for the first time fifty years ago this month, when I entered St. Bartholomew's Hospital as a student from Oxford. What struck me immediately was his youthful and debonair appearance, and his fine athletic figure. Morley, as we all called him, enjoyed life to the full. He was excellent company, and I have had many happy days with him playing golf, fishing, or shooting. He was a good shot, and formed part of a syndicate with a large sprinkling of Bart's men, who had a magnificent shoot near Thetford, where on several occasions I was his guest. Alas! those days are gone, never to return. But it was as a host that Morley really excelled. There must be hundreds of Cambridge Bart's men and their guests who remember his large room at 98, Harley Street, where all were welcome after the annual Cambridge Bart's dinner, and where Norman Moore recited as an annual ritual the story of Hairv Rachev (I've probably spelt that wrongly). After Norman Moore's death, Reginald Vick carried on the tradition admirably, being prompted, if ever there were any need, by the audience, who knew the story by that time as well as he did. Those were indeed great days of an epoch that has passed away. We salute both Morley and his times."

CHARLES CLAUD TWORT

M.D. ABERDEEN

Dr. C. C. Twort, sometime director of cancer research in the University of Manchester, died on Aug. 21 at the Hammersmith Hospital.

He was educated at Aberdeen University, where he graduated M.B. in 1909 and M.D. in 1913. In 1910 he spent some time in Paris as Thompson fellow working in the laboratory of Professor Levaditi at the Pasteur Institute. Later he joined his elder brother, the late F. W. Twort, F.R.S., at the Brown Institution, London. From there he published in 1913 an important paper on the pathogenicity of John's bacillus. His work as Rose fellow at St. Bartholomew's Hospital was interrupted by the 1914-18 war, during which the two brothers found themselves again in close association at the base laboratory at Salonika.

On demobilisation Twort held for a short period the post of director of the bacteriological department at the Royal Institute of Public Health in London. He had always been interested in cancer, and in 1926 he was

appointed director of cancer research at Manchester. The series of communications on mule-spinners' cancer, which he and his colleagues published in the next few years, culminated in the working out of a method of selection of non-carcinogenic oils. Finally he came south again, to settle at Southwick, Sussex, and during the late war he investigated the disinfection of closed atmospheres.

A. O. writes. "Twort's patience, thoroughness, and vision as an experimenter were outstanding, and withal he was so modest concerning his own achievements. Apart from his many original contributions to scientific medicine, it is as a lover of home, of his family, of his country, and of his friends that 'C. C.' will be most missed. Sincere and candid in his views, he had little or no use for the plaudits of the world. As a young Englishman abroad, where I first met him, Britain never had a better or more characteristic representative—just and dependable in all his relationships. To those honoured by his friendship, his cheerfulness, his loyalty, his courage, and his profound common sense were infectious and beyond price. While being the last to preach he set much store by the eternal values of charitableness, courtesy, kindness, and gentleness."

Dr. Twort was an adept in many forms of sport, he was a good long distance runner and a keen rugby player, he loved motoring, and he liked his game of golf.

In 1935 he married Miss Beatrice Bell Whetton, who survives him.

FLORENCE LOUIS

M.D. LOND., M.R.C.P.

Florence Louis, who died in London on Aug. 18, was an outstanding student of the Royal Free Hospital, where she graduated M.B. with honours in 1927. While a young resident, she discovered that she had diabetes and with characteristic courage decided that this should not influence her way of life. She married during her appointment as medical registrar at the Royal Free and had two sons. Then began the climb up the professional ladder that found her physician to the South London Hospital for Women at the time of her death at 48.

During the war she lost her much loved doctor-brother at Arrhen and her younger son—and from that time she drove herself unmercifully, seeing patients, doing coroners' post-mortems, and teaching students. During the last year she suffered a succession of illnesses so severe that those who saw her marvelled at her recovery. Her amazing courage and tenacity enabled her to surmount each crushing blow, for she knew too much to be in any doubt of their significance.

She was a lovable and lovely person, relentless in her pursuit of knowledge and in her efforts to help her patients. A woman of great integrity, who had suffered all her life from "the slings and arrows of outrageous fortune," she had not become embittered in the process. Her husband and son, Julian and Stephen Slade, have the sympathy of all her friends in the departure of so rare a person.

kink at the right extremity of the anastomosis, for at this point kinks cannot be undone by propulsive peristalsis, which has been abolished in the region of the anastomosis by the division of the circular muscle fibres. This is the reason for sewing up the lesser curvature end of the severed stomach and attaching the jejunum to it. The intact intestinal wall by contraction can undo any kink at the point where the bowel leaves the stomach, as it does during all the passage of the food along the normally kinked small intestine. I do not believe in the so called valve action. The length of the opening left in the stomach should be $2\frac{1}{8}$ in. This measurement, found by experience to be satisfactory, is assured by using a fenestrated clamp of the proper size.

The amount of stomach removed cannot be gauged accurately on the operation table as being three fourths or seven eighths as the case may be. It is better to take an anatomical point for its section—namely, the area where the territory supplied by the right gastro-epiploic artery meets that of the left. This point can usually be satisfactorily demonstrated. There is no need to be more radical than this. Indeed there is more danger of bad after effects in doing so.

Dumping and other symptoms following gastrectomy seem to be much rarer after operations performed according to this pattern.

St Mary's Hospital

CHARLES A. PANNETT

Public Health

Poliomyelitis

In England and Wales notifications of poliomyelitis in the week ended Sept 9 were: paralytic 327 (302), non-paralytic 186 (189), total 513 (491). The figures for the previous week are in parentheses. There was an increase of 25 paralytic cases and a decrease of 3 non-paralytic cases—net increase 22—compared with the preceding week. Non-paralytic cases in the week under review comprised 36.2% of the total, compared with 38.5% in the preceding week.

Stafford had an increase of 15 notifications compared with the week before, otherwise any increases were fairly generally distributed. Material decreases occurred in Durham (7) and Norfolk (8). The county areas of Cambridge and Radnor have notified no cases in the five weeks up to and including Sept 9. In the same period the following contributed 1 notification only: Suffolk (West), Isle of Ely, Soke of Peterborough, and Anglesey.

The uncorrected notifications for the week corresponding to that under review in 1947, 1948, and 1949 were 708, 76, and 306. Total uncorrected notifications for 1950 up to and including the week under review are 5126. The corresponding figures for 1947, 1948, and 1949 were 4984, 1214, and 2047.

Obituary

HERBERT MORLEY FLETCHER

M.A., M.D. CAMB., LL.D. BELF., F.R.C.P., F.R.A.C.P.

Dr H. Morley Fletcher, consulting physician to St Bartholomew's Hospital, died on Sept 9 at his home at Petworth in Sussex.

He was born in 1864 at Liverpool, the second son of Alfred Evans Fletcher and Sarah Morley, and he was educated at Mill Hill School and Trinity College, Cambridge, where he took his B.A. in 1887. Like his younger brother, Walter Fletcher, who later became the first secretary of the Medical Research Council, he was a fine athlete, and in 1888 he was elected president of the Cambridge University Athletic Club. After qualifying from Bart's in 1890 he spent some postgraduate years at Freiburg and Vienna, and in 1892 he contributed to *Ziegler's Beiträge* a paper on "die sogenannte Periarthritis Nodosa". In 1894 he published a translation of von Kahliden's *Methods of Pathological Histology*.

Morley Fletcher held house-appointments and demonstratorships at Bart's before he settled in consulting practice in London. He quickly won a name for himself not only as a general physician but also as a specialist in diseases of children. His appointment to the staff of the East London Hospital for Children was among the first of his honorary appointments, and fifty years ago there was no more stimulating centre for the study of children than that in which he took part with Eustace Smith, Coutts, and Gossage at the little Shadwell hospital in the East End. In 1904 he was appointed to the staff at Bart's, and soon after, with Hugh Thursfield, he was responsible for the development of the fine paediatric department there. From its foundation in 1928 he played a prominent part in the affairs of the British Paediatric Association, of which for many years he was treasurer, and in 1930 he succeeded Still and Cautley as its third president.

Of this side of his career H. O. O. writes: "Herbert Morley Fletcher in his time served many causes and had many interests, but perhaps it was as a physician for children that he would best like to be remembered. His devotion to paediatrics began early and continued to the end. The passing years, that brought age to others, seemed to leave him untouched, and to the last, among a younger generation trained on very different lines, he moved easily and happily, an honoured figure whose presence was always welcome. For if Morley Fletcher loved paediatrics he was loved by paediatricians."

Fletcher was on the staff of many other hospitals in London and the home counties, notably Queen Charlotte's Hospital, the Osborne Convalescent Home for Officers, Bushey Heath Hospital, Hertford County Hospital, the Metropolitan Convalescent Institution, and the Florence Nightingale Hospital. He was also a member of the medical consultative board of the Navy. He became a vice president of the medical college at Bart's, and he examined for the universities of Belfast, Cambridge, Durham, Glasgow, Sheffield, and for the Conjoint Board. He had been elected F.R.C.P. in 1900 and he later served the college as councillor and senior censor. During the 1914-18 war he worked with the rank of major at the 1st London General Hospital.

His retirement from Bart's in 1929 only meant that he was more readily available for other work. In 1933 he was appointed to the advisory committee on the administration of the Cruelty to Animals Acts, and he travelled up regularly from Petworth for meetings of the King's Fund. On his way to preside over meetings of the nursing recruitment committee of the Fund he would often drop in at the offices of the *Practitioner* to visit his son.

(Berresford)

After the 1914-18 war he was energetic in reviving the Association of Physicians of Great Britain, of which he was successively secretary, treasurer, and president. At the Royal Society of Medicine he had presided over the sections of diseases of children and of medicine, and in 1937 Queen's University, Belfast, conferred on him the honorary degree of LL.D. while he was presiding over the section of diseases of children at the B.M.A. meeting there. The Royal Australasian College of Physicians also made him an honorary fellow.

H. L. T. writes: "Herbert Morley Fletcher had many attributes, physical and intellectual, and throughout a long life he used them to the full for his own enjoyment and for giving pleasure to others. Outside the strict professional paths of hospital and practice he employed his administrative and social gifts in many directions. King Edward's Hospital Fund was an interest very close to him. He served it for over thirty years and less than four months ago he was visiting convalescent homes on its behalf. A good committee-man and a good chairman with a grasp of essentials, he had the power of keeping speakers to the point with an easy hand. He never lost his pleasure in athletics from the time when he was president of the C.U.A.C., and he rarely missed the Oxford and Cambridge sports. Indeed he enjoyed all social occasions. An attractive voice and a flow of entertaining conversation made him a delightful companion, and he liked a good cigar and a glass of wine. Friendliness, kindness, courtesy, and a boyish enthusiasm which never flagged, these he offered to fortune, and fortune gave him two long and happy married lives."

Dr. Morley Fletcher's first wife, Ethel Frances Crossley, of Halifax, by whom he had two sons and three daughters, died in 1918. One of his daughters married Mr. H. U. Willink, whose sister, Mary Christina Willink, became his second wife. There are two daughters of this marriage.

O. M. H. H. writes: "I met Morley Fletcher for the first time fifty years ago this month, when I entered St. Bartholomew's Hospital as a student from Oxford. What struck me immediately was his youthful and debonaire appearance, and his fine athletic figure. Morley, as we all called him, enjoyed life to the full. He was excellent company, and I have had many happy days with him playing golf, fishing, or shooting. He was a good shot, and formed part of a syndicate with a large sprinkling of Bart's men, who had a magnificent shoot near Thetford where on several occasions I was his guest. Alas! those days are gone, never to return. But it was as a host that Morley really excelled. There must be hundreds of Cambridge Bart's men and their guests who remember his large room at 98, Harley Street, where all were welcome after the annual Cambridge Bart's dinner, and where Norman Moore recited as an annual ritual the story of Harry Rachev (I've probably spelt that wrongly). After Norman Moore's death, Reginald Vick carried on the tradition admirably, being prompted, if ever there were any need, by the audience, who knew the story by that time as well as he did. Those were indeed great days of an epoch that has passed away. We salute both Morley and his times."

CHARLES CLAUD TWORT

M.D. ABERD.

Dr. C. C. Twort, sometime director of cancer research in the University of Manchester, died on Aug. 21 at the Hammersmith Hospital.

He was educated at Aberdeen University, where he graduated M.B. in 1909 and M.D. in 1913. In 1910 he spent some time in Paris, as Thompson fellow working in the laboratory of Professor Levaditi at the Pasteur Institute. Later he joined his elder brother, the late F. W. Twort, F.R.S., at the Brown Institution, London. From there he published in 1913 an important paper on the pathogenicity of John's bacillus. His work as Rose fellow at St. Bartholomew's Hospital was interrupted by the 1914-18 war, during which the two brothers found themselves again in close association at the base laboratory at Salonika.

On demobilisation Twort held for a short period the post of director of the bacteriological department at the Royal Institute of Public Health in London. He had always been interested in cancer, and in 1926 he was

appointed director of cancer research at Manchester. The series of communications on mule-spinners' cancer, which he and his colleagues published in the next few years, culminated in the working out of a method of selection of non-carcinogenic oils. Finally he came south again, to settle at Southwick, Sussex, and during the late war he investigated the disinfection of closed atmospheres.

A. C. writes: "Twort's patience, thoroughness, and vision as an experimenter were outstanding, and withal he was so modest concerning his own achievements. Apart from his many original contributions to scientific medicine, it is as a lover of home, of his family, of his country, and of his friends that 'C. C.' will be most missed. Sincere and candid in his views, he had little or no use for the plaudits of the world. As a young Englishman abroad, where I first met him, Britain never had a better or more characteristic representative—just and dependable in all his relationships. To those honoured by his friendship, his cheerfulness, his loyalty, his courage, and his profound common sense were infectious and beyond price. While being the last to preach he set much store by the eternal values of charitableness, courtesy, kindness, and gentleness."

Dr. Twort was an adept in many forms of sport, he was a good long distance runner and a keen rugby player. He loved motoring, and he liked his game of golf.

In 1935 he married Miss Beatrice Bell Whitton, who survives him.

FLORENCE LOUIS

M.D. LOND., M.R.C.P.

Florence Louis, who died in London on Aug. 16, was an outstanding student of the Royal Free Hospital, where she graduated M.B. with honours in 1927. While a young resident, she discovered that she had diabetes and with characteristic courage decided that this should not influence her way of life. She married during her appointment as medical registrar at the Royal Free and had two sons. Then began the climb up the professional ladder that found her physician at the South London Hospital for Women at the time of her death at 46.

During the war she lost her much-loved doctor-brother at Arnhem and her younger son—and from that time she drove herself unmercifully, seeing patients, doing coroner's post-mortems and teaching students. During the last year she suffered a succession of illnesses so severe that those who saw her marvelled at her recovery. Her amazing courage and tenacity enabled her to surmount each crushing blow, for she knew too much to be in any doubt of their significance.

She was a lovable and lovely person, relentless in her pursuit of knowledge and in her efforts to help her patients. A woman of great integrity, who had suffered all her life from 'the slings and arrows of outrageous fortune,' she had not become embittered in the process. Her husband and son, Julian and Stephen Slade, have the sympathy of all her friends in the departure of so rare a person.

APPROVED NAMES FOR DRUGS

THE British Pharmacopoeia Commission has issued the following supplementary list of approved names, some of which were announced last year (see *Lancet*, 1949, ii, 354)

Approved Name	Other Names
Alphaprodine	α 1 3 Dimethyl 4 phenyl 4 propionoxy piperidine
Amidone	6 Dimethylamino 4 4 diphenylheptan-3-one
Antazolone	Physeptone 2 N-Benzylanilinoethyliminazoline
Benzhexol	Antistim Histostab 1-cyclohexyl 1 phenyl 3 piperidine 1-propanol
Betaprodine	Artane is the hydrochloride β 1 3 Dimethyl 4 phenyl-4 propionoxy piperidine
Chloramphenicol	D (-) <i>threo</i> 2 Dichloroacetamido 1 p-nitrophenyl 1 3 propanediol
Chlorcyclizine	Chloromyceol ($\pm$) 1-(p-Chlorobenzhydryl)-4-methyl piperazine
Dapsone	Histanin is the hydrochloride
Decamethonium iodide	4 4 Diaminodiphenyl sulphone
Dexamphetamine	Decamethylene 1 10 bistrimethyl ammonium di iodide C 10
Diethazine	(+) Amphetamine Dexedrine is the sulphate
Dimethyltubocurarine iodide	N 2 Diethylaminoethylphenothiazine
Diphenhydramine	Diparcol is the hydrochloride Dimethyl ether iodide of (+) tubocurarine
Ethyl pyrophosphate	Benzhydryl 2 dimethylaminoethyl ether Bonadryl is the hydrochloride Tetraethyl pyrophosphate
Gallamine	T E P P 1 2 3 Tri(2-diethylaminoethoxy) benzene
Hexamethonium iodide	Flaxedil is the triethiodide Hexamethylene 1 6 bistrimethyl ammonium di iodide C 6
Hydroxypethidine	Ethyl 4 m-hydroxyphenyl 1 methyl piperidine 4-carboxylate
Isoamidone	6 Dimethylamino 5 methyl-4 4-diphenylhexan-3-one
Isoprenaline	iso-Propylnoradrenaline Aloudrine is the sulphate, Neo Epinephrine is the sulphate, Isupren is the hydrochloride, Neodrenal is the sulphate
Ketobemidone	4 m-Hydroxyphenyl 1 methyl 4 propionylpiperidine
Lignocaine	Diethylaminoacet m 2 xylidide
Lindane	Xylacaine is the hydrochloride γ 1 2 3 4 5 6 Hexachlorocyclohexane
Menadoxime	Ammonium salt of 2-methylnaphthoquinone 4 oxime O-carboxymethyl ether
Mephensesin	Kaplon Soluble 1 2 Dihydroxy 3 (2'-methylphenoxy) propane
Mepyramine	Myanasin N N'-Methoxybenzyl N N'-dimethyl N 2 pyridylethylenediamine
Methacholine chloride	Anthisan is the hydrogen malate, Neo antergan is the hydrogen malate
Methadol	Acetyl 6-methylcholine hydrochloride Meclohy Chloride, Amecol
Methadyl acetate	6 Dimethylamino-4 4-diphenylheptan-3-ol
Methoin	6 Dimethylamino 4 4 diphenyl 3 heptyl acetate
Mustine	5 Ethyl 3 methyl 5 phenylhydantoin Mesoloin
Naphazoline	Di (2-chloroethyl)dimethylamino
Pentamethonium iodide	Nitrogen mustard is the hydrochloride
Phenadoxone	2 (Naphthyl 1 methyl)iminazoline
Phenindamine	Phivine is the nitrate Pentamethylene 1 5 bistrimethyl ammonium di iodide C 5
Phenylpropanolamine	6 Morpholine 4 4-diphenylheptan-3-one
Potassium menaphtho sulphate	Heptalgin is the hydrochloride 1 2 3 4 Tetrahydro 2 methyl 9 phenyl 2 azafurone
Promethazine	Thephorin is the hydrogen tartrate 2 Amine 1 phenyl 1 propanol
Quinalbarbitone sodium	Propadrine is the hydrochloride
Thiacetazone	Dipotassum 2 methyl 1 4 disulphato naphthalene dihydrate
Tolazoline	Λ (2-Dimethylamino n-propyl)phenothiazine
Troxidone	Phenergan is the hydrochloride
Tripeleminamine	Monosodium derivative of 5 allyl 5 (1-methylbutyl)barbituric acid
	Second Sodium
	4-Acetamidobenzaldehyde thio-semicarbazone
	2-Benzyliminazoline
	Prisol is the hydrochloride
	3 5 5 Trimethylloxazolidine 2 4 dione
	Tridone
	N-Benzyl N,N-dimethyl N 2 pyridylethylmethanamine
	Pyribenzamine is the hydrochloride

COLONIAL SERVICE AND THE N H S

UNDER the National Health Service (Amendment) Act 1949, doctors, dentists, and nurses who have been employed in the National Health Service and who take short-service engagements—not exceeding six years—in the Colonial Research Service, the Colonial Medical Service, the Queen Elizabeth Colonial Nursing Service, or the services of Colonial governments can, if they wish, preserve their superannuation in the N H S. An outline of the scheme is set out in circular N.H.S. (50) 85 and further details can be had from the Health Services Superannuation Division, Ministry of Health, Government Building, Honeypot Lane, Stanmore, Middlesex.

CHANGING DOCTORS

AFTER consultation with the General Medical Services Committee and the Executive Councils Association, the Minister of Health has decided to place some restriction on the patient's right to transfer immediately from one National Health Service doctor to another. In future the patient, unless he has changed his address, must either obtain his present doctor's consent in writing or else send his medical card to the local executive council together with a letter notifying his intention to transfer. In the latter event the patient will normally be able to choose a new doctor 14 days after the council has received the card and letter, but the actual date on which he can transfer will be stated by the council when it returns his medical card. Patients who have moved to a different address will still be able to transfer immediately, by taking their medical card to the doctor of their choice. Details of the new arrangements are given in circular E.O.L. 98/50 and its appendix.

MIDWIVES UNDER THE NATIONAL HEALTH SERVICE

In the last two years the Central Midwives Board¹ have been clearing their roll of the names of those who have retired from practice died, or failed to notify their wish to remain on it. There were 64,490 names on the register on March 31, 1950—a fall of over 12,500 since the previous year. Those who notified their intention to practise during 1949, however, numbered 18,053, or 234 more than the number for 1948. The number practising has been rising steadily since 1942, and the proportion trained under the modern system, which came into force in 1939, has now risen to nearly half. Over 70% of those practising in 1949 were between the ages of 26 and 50—in other words they were experienced midwives in the best years of their working lives. The training is thorough, and the examination pass rate is good. In 1949, just under a quarter failed to get through the first examination and about an eighth failed to get through the second. Wastage amounted to only 8.6% of registrations, and was mostly from among those doing the first period of training.

The National Health Service has had one adverse effect on training: hospital confinements increased so much that it was difficult to give pupil midwives a thorough training on the district. The board, together with the Central Midwives Boards for Scotland and for Eire, and the Joint Nursery and Midwives Council for Northern Ireland, discussed the idea of reducing the number of district cases which a pupil midwife is required to conduct during her second period of training, but decided that this would lower the standard of training. The pupil must therefore still conduct her 10 district cases over a period of three months, in addition to the 20 cases she conducts in hospital during part 1 training. Experienced midwives of the type we have all come to value owe much to this thorough supervised teaching during their training years.

The board believe the organisation of midwifery schools could be improved and supports the view of the Working Party on Midwives that experiments should be made to determine the relation of such schools to hospitals. They are conducting limited experiments in five or six schools in England and Wales, but note that at least a year must pass before they can assess results.

The training of midwives and pupil midwives in the administration of gas and air analgesia has gone on very well and some 19,000 are now proficient. Over 11,118 of these were in practice in 1949, representing about 60% of practising midwives. The Chassar Moir attachment has been

¹ Annual Report for the year ended March 31 1950. London: Published for the Board by Spottiswoode, Ballantyne & Co. 1950. Pp. 23.

tried in Hertfordshire with the board's consent, and has given good results. The report comments on the administrative inconvenience of maternity services divided under 'separate types of authority' each entrusted with powers and duties to operate a particular section of the service — but it does not develop this theme.

MEDICAL DEFENCE UNION

At the annual meeting of the Medical Defence Union on Sept 19 Mr Ivor Back, in his first presidential address said that though some thought that the increase in the subscription announced last year would lead to a considerable loss of membership, this fear had not been realised, and the membership figure stood at 34 500. The council was disturbed by the great increase in the number of complaints, some times quite trivial, brought against doctors and dentists since the National Health Service came into being. When these complaints were heard by a medical and/or dental service committee the respondent practitioner was not allowed to be represented by a solicitor or other paid advocate, though he might bring a colleague to advise and assist him. There was a division of opinion in the council as to whether this ruling acts to the detriment of the respondent or not but the opinion was generally held that the chairman of all service committees should be legally qualified, to ensure, as far as possible, some uniformity of procedure. Meanwhile the British Medical Association had brought forward proposals for improving the procedure of these committees and for shortening the time within which complaints may be lodged, and these met with the approval of the M.D.U. Another matter which continued to cause concern to the union was that of death under anaesthesia and during the past year a conference had been held with representatives of the Royal Colleges the B.M.A. and the Association of Anaesthetists.

The annual report which was presented at the meeting, showed that 2125 members sought the union's assistance during 1949 and 199 cases were passed to the solicitors. Of the 74 which were allegations of professional negligence, 10 came to court and 8 were won. Probably the most noteworthy single event in which the union was able to help its members during 1949 was the circular from the Ministry of Health to hospital boards drawing attention to the alleged right of these authorities when sued by or on behalf of a patient for the alleged negligence on the part of their medical staff, to obtain an indemnity from the members of the staff concerned. Two implications of this circular the report says are that the importance of membership of the union is now greater than ever and that members must take great care before they give a statement to the management of their hospital on any matter of complaint by a patient since any such statement may afterwards be used to their own detriment. "The golden rule for the future must be that a statement should not be made in a case of a complaint by a patient, if there is or appears to be the slightest possibility of litigation, until the facts have been reported to the union and any proposed statement approved."

University of London

Prof. E. K. Tratman, F.R.S. & C.S., has been appointed to the chair of dental surgery at University College Hospital Medical School, from Oct 1.

On Tuesday Oct 17, at 5 P.M., at St Mary's Hospital Medical School, W 2 Prof U S von Euler (Stockholm) is to give a lecture on Hormones of the Sympathetic Nervous System and the Adrenal Medulla.

University of Sheffield

Prof F A E Crew F.R.S. will give the opening address of the session to the faculty of medicine on Wednesday Oct 11 at 5 P.M. He is to speak on the Changing Emphasis of Medicine.

Maida Vale Hospital

On Friday Oct 6 at 5 P.M. Sir Hugh Cairns will give the opening address of the session at this hospital, London, W 9, on Colloid Cryst of the Third Ventricle.

London School of Hygiene

On Thursday Oct 5 at 5.15 P.M. Sir Philip Manson Bahr will give the first of an annual series of Manson lectures. He is to speak on Patrick Manson the Father of Tropical Medicine. Further particulars will be found in our advertisement columns.

St Thomas's Hospital

Twelve beds in the St Thomas's Hospital group have been set aside for psychiatric patients.

London County Medical Society

A meeting of this society will be held at the Royal Free Hospital (North Western Branch), Lawn Road, Hampstead, N W 3, on Wednesday, Oct 4 at 3 P.M.

Hunterian Society

Lord Horder will open the library and museum of this society during the annual party, which is being held at 41 Portland Place, London, W 1, on Thursday, Oct 5, at 6 P.M.

London Lock Hospital

The wards of this hospital in Dean Street, W 1, have been reopened, and male patients with any of the sequelae of venereal disease acute or chronic, skin, heart or nervous system, can now be accepted.

The Institute of Dermatology

On Oct 3 the winter course of lectures of the institute will begin at St John's Hospital for Diseases of the Skin, Lisle Street London W C 2. The course will include lecture-demonstrations on medical mycology and lectures on branches of pathology relating to diseases of the skin.

Liddle Prize

The subject chosen for the 1952 award of this prize is the Effect of Hormones on the Reaction of the Tissues to Injury. Further particulars may be had from the dean of the London Hospital Medical College, Turner Street London E 1. Essays must reach the hospital not later than July 31, 1952.

International Congress of Cardiology

At the congress held in Paris from Sept 3 to 9, the British Government was represented by Prof. Crighton Bramwell, and the Medical Research Council by Prof. John McMichael. Upwards of 50 members of the British Cardiac Society attended the congress, their representative being Sir John Parkinson.

Control of Illegal Opium Traffic

A United Nations committee is reported by B.U.P. to have approved, at a meeting in Geneva, the principle of an international opium monopoly to be set up within the United Nations to end illegal traffic in the drug. The committee's report which will be submitted to the United Nations Narcotic Commission, recommends that this monopoly should have the right of inspection in the territories of nations adopting the agreement.

Institute of Obstetrics and Gynaecology

On the retirement of Prof. James Young from the chair of obstetrics and gynaecology at the Postgraduate Medical School of London at Hammersmith Hospital the committee of management of the Institute of Obstetrics and Gynaecology have appointed Mr Charles D. Read to the newly created post of director of the institute, which embraces the clinical teaching and research facilities of Queen Charlotte's Maternity Hospital the Chelsea Hospital for Women and the department of obstetrics and gynaecology of the Postgraduate School at Hammersmith Hospital. Mr Read who has accepted the post on a part-time basis, will take up his duties on Oct 1.

Women Doctors for American Army

Authorisation has been given for women to be commissioned in the Medical Dental, Veterinary and Medical Service Corps Reserves of the U.S. Army and assigned to active duty. They will be eligible for service in every type of military medical facility, with the exception of forward medical installations in combat zones. In making this announcement Major-General R. W. Bliss the surgeon general of the U.S. Army, said: "It has long been my opinion that restrictions upon the practice of medicine, dentistry, and other related specialties in the Army due solely to the sex of the individual are discriminatory. We are happy, therefore, to be able to offer women Reserve commissions and to bring them on active duty as Reserve officers on the basis of exact equality with men in their respective fields. But we shall not rest on this achievement. We shall pursue every opportunity to extend this equality by the enactment of legislation which will ultimately provide medical women status in the Regular Army."

Notes and News

APPROVED NAMES FOR DRUGS

THE British Pharmacopœia Commission has issued the following supplementary list of approved names, some of which were announced last year (see *Lancet*, 1949, ii, 354)

Approved Name	Other Names
Alphaprodine	α 1 3 Dimethyl 4 phenyl-4 propionoxy piperidine
Amidone	6 Dimethylamino 4 4 diphenylheptan-3-one Physeptone
Antazoline	2 N-Benzylanilinomethyliminazoline Antistin Histostab
Benzhexol	1 cyclohexyl 1 phenyl 3 piperidine 1 propanol Artane is the hydrochloride
Betaprodine	β 1 3 Dimethyl 4 phenyl-4 propionoxy piperidine
Chloramphenicol	D (-) threo 2 Dichloroacetamido 1 p nitrophenyl 3 propanediol Chloromycetin
Chlorcyclizine	($\pm$) 1-(p Chlorobenzhydryl)-4 methyl piperazine Histantin is the hydrochloride ~ DI paralene is the hydrochloride
Dapsone	4 4 Diaminodiphenyl sulphone
Decamethonium iodide	Decamethylene 1 10 bistrimethyl ammonium di iodide C 10
Dexamphetamine	(+) Amphetamine Dexedrine is the sulphate
Diethazine	N 2 Diethylaminoethylphenothiazine Diparcol is the hydrochloride
Dimethyltubocurarine iodide	Dimethyl ether iodide of (+) tubocurarine
Diphenhydramine	Benzhydryl 2 dimethylaminoethyl ether Benadryl is the hydrochloride
Ethyl pyrophosphate	Tetraethyl pyrophosphate T E P P
Gallamine	1 2 3 Tri(2 diethylaminoethoxy) benzene Flaxedil is the triethiodide
Hexamethonium iodide	Hexamethylene 1 6 bistrimethyl ammonium di iodide C 6
Hydroxypothidine	Ethyl 4 m hydroxyphenyl 1 methyl piperidine 4-carboxylate
Isoamidone	6 Dimethylamino 3 methyl-4 4-di phenylhexan 3-one isoPropyloradrenaline
Isoprenaline	Aleudrine is the sulphate Neo Epinafe is the sulphate Isupren is the hydrochloride Neodrenal is the sulphate
Ketobemidone	4-m Hydroxyphenyl 1 methyl-4 propionylpiperidine Diethylaminoacet-m 2 xylidide
Lignocaine	Xylocaine is the hydrochloride 1 2 3 4 6 Hexachlorocyclohexane
Lindane	hexane
Menadoxime	Ammonium salt of 2 methyl-naphthoquinone 4-oxime O-carboxymethyl ether Kaplon Soluble
Mephenezin	1 2 Dihydroxy 3 (2 methylphenoxy) propane Myanazin
Mepyramine	N p Methoxybenzyl N'N'-dimethyl N-2 pyridylethylenediamine Anthisan is the hydrogen maleate Neo antergan is the hydrogen maleate
Methacholine chloride	Acetyl β methylcholine hydrochloride Mechoyl Chloride, Ameacol
Methadol	6 Dimethylamino 4 4-diphenylheptan-3-ol
Methadyl acetate	6 Dimethylamino-4 4 diphenyl 3 heptyl acetate
Methoin	5 Ethyl 3 methyl 5 phenylhydantoin
Mustine	Mesontoin DI (2 chloroethyl)methylamine Nitrogen mustard is the hydrochloride
Naphazoline	2 (Naphthyl 1 methyl)iminazoline Privine is the nitrate
Pentamethonium iodide	Pentamethylene 1 5 bistrimethyl ammonium di iodide C 5
Phenadoxone	6 Morpholine 4 4 diphenylheptan-3-one Heptalgin is the hydrochloride
Phenindamine	1 2 3 4 Tetrahydro 2 methyl 9 phenyl 2 azaflorene Thephorin is the hydrogen tartrate
Phenylpropanolamine	2 Amino 1 phenyl 1 propanol Propadrine is the hydrochloride

Promethazine	Λ (2 Dimethylamino n propyl)pheno thiazine Phenergan is the hydrochloride Monosodium derivative of 5 allyl 5 (1 methylbutyl)barbituric acid Seconal Sodium
Quinalbarbitone sodium	4 Acetamidobenzaldehyde thiosemi carbazone
Thiacetazone	2 Benzyliminazoline Priscoil is the hydrochloride
Tolazoline	3 5 5 Trimethyloxazolidine 2 4 dione Tridione
Troxidone	Λ Benzyl Λ Λ dimethyl Λ 2 pyridyl ethylenediamine
Triplennamine	Pyribenzamine is the hydrochloride

COLONIAL SERVICE AND THE N H S

UNDER the National Health Service (Amendment) Act, 1949, doctors, dentists, and nurses who have been employed in the National Health Service and who take short-service engagements—not exceeding six years—in the Colonial Research Service, the Colonial Medical Service, the Queen Elizabeth Colonial Nursing Service, or the services of Colonial governments can, if they wish, preserve their superannuation in the N H S. An outline of the scheme is set out in circular R.H.S. (50) 85 and further details can be had from the Health Services Superannuation Division, Ministry of Health, Government Building, Honeypot Lane, Stanmore, Middlesex.

CHANGING DOCTORS

AFTER consultation with the General Medical Services Committee and the Executive Councils Association, the Minister of Health has decided to place some restriction on the patient's right to transfer immediately from one National Health Service doctor to another. In future the patient, unless he has changed his address, must either obtain his present doctor's consent in writing or else send his medical card to the local executive council together with a letter notifying his intention to transfer. In the latter event the patient will normally be able to choose a new doctor 14 days after the council has received the card and letter, but the actual date on which he can transfer will be stated by the council when it returns his medical card. Patients who have moved to a different address will still be able to transfer immediately, by taking their medical card to the doctor of their choice. Details of the new arrangements are given in circular E.C.L. 98/50 and its appendix.

MIDWIVES UNDER THE NATIONAL HEALTH SERVICE

IN the last two years the Central Midwives Board¹ have been clearing their roll of the names of those who have retired from practice died, or failed to notify their wish to remain on it. There were 64,490 names on the register on March 31, 1950—a fall of over 12,500 since the previous year. Those who notified their intention to practise during 1949, however numbered 18,053, or 234 more than the number for 1948. The number practising has been rising steadily since 1942, and the proportion trained under the modern system, which came into force in 1939, has now risen to nearly half. Over 70% of those practising in 1949 were between the ages of 26 and 50—in other words they were experienced midwives in the best years of their working lives. The training is thorough, and the examination pass rate is good. In 1949, just under a quarter failed to get through the first examination and about an eighth failed to get through the second. Wastage amounted to only 8.6% of registrations, and was mostly from among those doing the first period of training.

The National Health Service has had one adverse effect on training: hospital confinements increased so much that it was difficult to give pupil midwives a thorough training or the district. The board, together with the Central Midwives Boards for Scotland and for Eire, and the Joint Nursery and Midwives Council for Northern Ireland, discussed the idea of reducing the number of district cases which a pupil midwife is required to conduct during her second period of training, but decided that this would lower the standard of training. The pupil must therefore still conduct her 10 district cases over a period of three months, in addition to the 20 cases she conducts in hospital during part I training. Experienced midwives of the type we have all come to value owe much to this thorough supervised teaching during their training years.

The board believe the organisation of midwifery schools could be improved and supports the view of the Working Party on Midwives that experiments should be made to determine the relation of such schools to hospitals. They are conducting limited experiments in five or six schools in England and Wales, but note that at least a year must pass before they can assess results.

The training of midwives and pupil midwives in the administration of gas and air analgesia has gone on very well and some 19,000 are now proficient. Over 11,118 of these were in practice in 1949 representing about 60% of practising midwives. The Chassar Moir attachment has been

PROPAGATION OF THE UNFIT*

L S PENROSE

M.A., M.D. Camb

GALTON PROFESSOR OF EUGENICS IN THE UNIVERSITY OF LONDON, AT UNIVERSITY COLLEGE

In mental deficiency work we meet one special problem which does not occur in quite the same form, requiring immediate decision, in any other branch of medical practice, and for which our medical training gives us little or no preparation. I refer to the question of segregating high grade defectives because we think that, on social or biological grounds, they ought not to have children. Cases can be judged by social standards based either upon moral or upon economic considerations, but here I shall confine myself mainly to the biological 'fitness' of the mentally defective for parenthood.

WHAT IS BIOLOGICAL FITNESS?

The term 'fitness' in its ordinary use conjures up a picture of robust health—ability to go a ten mile walk before breakfast, including a swim in icy water. A parallel use of the term was intended, for example, by Pearson (1912a) when it was demonstrated that alcoholism was as common among the healthy as among the unhealthy, here, fitness was equated to length of life.

Educational psychology lays stress on something else—namely, scholastic fitness, that is, ability to do sums correctly, to remember large quantities of arbitrary facts, and to reason clearly in the abstract. Personnel selectors lay stress on the desirability of emotional stability, freedom from anxiety, and facility in making personal contacts. None of these ideas agree with what is meant by 'fitness' in a biological sense, though such qualities as health, in particular, may be correlated with the biological requirements.

What, then, constitutes biological fitness? Darwin emphasised survival, which is closely related to health, but in fact fertility matters most in evolution through natural selection, survival is a necessary but insufficient condition. Net fertility can be measured by the number of offspring who reach the mean age at which the parent reproduced. Thus stillbirths and deaths in infancy do not enhance the fertility of the parent. Since biological fitness and net fertility are synonymous, the unfit are, by definition, those who are unable to propagate efficiently.

Eugenists have frequently pointed out that civilisation tends to preserve the unfit, but, unless children are born to those so preserved, there is no effect on posterity. It is easy to quote instances in which medical science does actually alter fitness. Sometimes it produces an increase—e.g., when a juvenile diabetic is nurtured to an adult age or when a case of retinoblastoma is surgically cured. At other times, as when we segregate a high grade defective or when a patient is sterilised, fitness is directly diminished by medical procedure in the interests of the individual's mental or physical health.

As a consequence of our artifices, a general decline of physique and intelligence in civilised communities has been predicted. Pearson (1912b) blamed both medical and social changes.

"We are already feeling the dearth of able men in all departments of activity. We have now consciously to undertake the work of natural selection ourselves, for we have suspended Nature's effective but oft-times harsh methods of raising our stock. We have to check the fertility of the unfit and encourage that of the fit."

Others, with their eyes on statistics of differential birth rate have considered the problem to be of a more general character. For example, Cattell (1937) wrote "Under

every system of civilisation yet known, there has been an ineradicable tendency for the population to be recruited from the submen." The observations on which such arguments are based include a formidable array of facts. Special attention has been drawn to these facts in recent years, but they do not necessarily concern new processes.

Differential birth rate is a phenomenon commonly found when cultural or religious groups are compared. More striking and regular are the economic gradations in family size, and of particular interest is the differential birth rate with respect to mental ability (Burt 1946, Thomson 1947). Also noticeable are the large family sizes found among the physically disabled—among those suffering from blindness, deafness, epilepsy, or rheumatism—though such data must be carefully corrected for selection of abnormally large sibships on account of affected cases (Jones 1934). In general, eugenic ideas have crystallised in the conception of the social-problem group, from which our high grade defective patients are drawn—a submerged tenth of the population, poverty-stricken, unhealthy, antisocial, and poorly endowed intellectually but with greatly increased fertility (Lidbetter 1933). It is often assumed that such a group could not exist except in a civilised society and that it is the product of too much social care. Nothing could be more absurd, since the group is, by its nature and by definition, looked after inadequately.

From the point of view of the biologist, this group is "fit" because it has a high fertility, though from the ordinary social point of view the members are "unfit". Actually, its separation from the rest of the community is arbitrary, and implies an assumption similar to that made a century ago by students of criminality and sponsored by Lombroso (1887). The subcultural, or social problem, human being has separate existence no more than the criminal type. Poor physique, criminality, inferior intellectual stature, and low economic status can easily be shown to be correlated, but the causes of the associations are not simple (Goring 1913). We must beware of assuming that the social problem group exists because it has a name. For the purpose of discussing biological fitness, however, it may be convenient to assume its existence even if this involves considerable over simplification.

FERTILITY AND INTELLIGENCE

Lately much attention has been given to the problem of the general intelligence level in the population. The relatively high fertility prevalent in the social problem group is thought to imply that its numbers will increase to the detriment of the rest of the community. As I have previously often pointed out, such predictions are based upon particular assumptions about the genetical structure of the population, and there are important possibilities which have been overlooked. To get a clear picture, we must first of all examine the relation of fertility to intelligence over the whole range of values—that is to say, from the most brilliant to the dullest, even including idiots.

All investigators agree that the fertility of the most intelligent is low, and that, within most of the normal range, fertility rises steadily as intelligence quotient (I.Q.) falls. Idiots, however, are infertile even if they survive infancy, so, at some point in the scale of I.Q., fertility must reach a maximum. The net fertility of persons with intellects of very low grade has not been at all fully investigated. A good way of examining the problem would be to compare the intelligence distribution of the population at birth with the distribution of intelligence among the parents of every child born. Parents of two children would be represented twice in the sample and parents of three children three times, and so on.

* A paper read to the North West Metropolitan Regional Mental Deficiency Society on Feb 27, 1950.

Mothercraft Exhibition

The 1950 mothercraft exhibition and conference is to be held at the Central Hall, Westminster, London, S W 1, from Nov 4 to 14

Air Disinfection and Sterilisation

A symposium on this subject will be held by the micro biological panel of the Society of Chemical Industry on Wednesday, Oct 11, at 3 P M at 11, Chandos Street, London, W 1. The speakers will include Dr R E O Williams and Dr R B Bourdillon

Royal Army Medical College

Lectures will be given at the college (entrance John Ishp Street), London, S W 1, during this winter on Thursdays, at 5 P M. They will be open without fee to both Service and civilian doctors. Sir William MacArthur will give the first, on Oct 12, on the History of Smallpox in the British Isles. Particulars of further lectures will be found in our weekly diary

British Journal of Ophthalmology and Ophthalmic Literature

The publication of this journal has been taken over by the British Medical Association. The editor of the journal should be addressed at the Institute of Ophthalmology, Judd Street, London, W C 1

Dr J Greenwood Wilson will take office as chairman of the council of the Royal Sanitary Institute on Oct 1

From Sept 17 to Oct 5 Mr St J D Buxton is visiting Greece for the third time at the invitation of the Greek Recovery Programme Committee, to advise on the rehabilitation of the wounded and civilians and the development of a national service for the care of cripples

Dame Katherine Watt, D B E, B R C chief nursing adviser to the Ministry of Health, is retiring at the end of this month. Dame Katherine was matron in chief of Princess Mary's R A F Nursing Service before she joined the Ministry in 1939 as principal matron for the Emergency Medical Service. She was appointed to her present post in 1948

PROPAGATION OF THE UNFIT*

L S PENROSE

M.A., M.D Camb

GALTON PROFESSOR OF EUGENICS IN THE UNIVERSITY OF LONDON, AT UNIVERSITY COLLEGE

In mental deficiency work we meet one special problem which does not occur in quite the same form, requiring immediate decision in any other branch of medical practice, and for which our medical training gives us little or no preparation. I refer to the question of segregating high grade defectives because we think that, on social or biological grounds, they ought not to have children. Cases can be judged by social standards based either upon moral or upon economic considerations but here I shall confine myself mainly to the biological "fitness" of the mentally defective for parenthood.

WHAT IS BIOLOGICAL FITNESS?

The term "fitness" in its ordinary use conjures up a picture of robust health—ability to go a ten mile walk before breakfast including a swim in icy water. A parallel use of the term was intended, for example, by Pearson (1912a) when it was demonstrated that alcoholism was as common among the healthy as among the unhealthy, here fitness was equated to length of life.

Educational psychology lays stress on something else—namely, scholastic fitness, that is ability to do sums correctly, to remember large quantities of arbitrary facts, and to reason clearly in the abstract. Personnel selectors lay stress on the desirability of emotional stability, freedom from anxiety, and facility in making personal contacts. None of these ideas agree with what is meant by "fitness" in a biological sense, though such qualities as health in particular, may be correlated with the biological requirements.

What then constitutes biological fitness? Darwin emphasised survival, which is closely related to health, but in fact fertility matters most in evolution through natural selection. Survival is a necessary but insufficient condition. Net fertility can be measured by the number of offspring who reach the mean age at which the parent reproduced. Thus stillbirths and deaths in infancy do not enhance the fertility of the parent. Since biological fitness and net fertility are synonymous the unfit are by definition, those who are unable to propagate efficiently.

Eugenists have frequently pointed out that civilisation tends to preserve the unfit, but, unless children are born to those so preserved, there is no effect on posterity. It is easy to quote instances in which medical science does actually alter fitness. Sometimes it produces an increase—e.g. when a juvenile diabetic is nurtured to an adult age or when a case of retinoblastoma is surgically cured. At other times, as when we segregate a high-grade defective or when a patient is sterilised, fitness is directly diminished by medical procedure in the interests of the individual's mental or physical health.

As a consequence of our artifices, a general decline of physique and intelligence in civilised communities has been predicted. Pearson (1912b) blamed both medical and social changes.

We are already feeling the dearth of able men in all departments of activity. We have now consciously to undertake the work of natural selection ourselves for we have suspended Nature's effective but oft-times harsh methods of raising our stock. We have to check the fertility of the unfit and encourage that of the fit.

Others, with their eyes on statistics of differential birth rate have considered the problem to be of a more general character. For example Cattell (1937) wrote "Under

every system of civilisation yet known, there has been an ineradicable tendency for the population to be recruited from the submen." The observations on which such arguments are based include a formidable array of facts. Special attention has been drawn to these facts in recent years, but they do not necessarily concern new processes.

Differential birth-rate is a phenomenon commonly found when cultural or religious groups are compared. More striking and regular are the economic gradations in family size and of particular interest is the differential birth rate with respect to mental ability (Burt 1946, Thomson 1947). Also noticeable are the large family sizes found among the physically disabled—among those suffering from blindness, deafness, epilepsy, or rheumatism—though such data must be carefully corrected for selection of abnormally large sibships on account of affected cases (Jones 1934). In general, eugenic ideas have crystallised in the conception of the social-problem group, from which our high grade defective patients are drawn—a submerged tenth of the population, poverty-stricken, unhealthy, antisocial, and poorly endowed intellectually but with greatly increased fertility (Lidbetter 1933). It is often assumed that such a group could not exist except in a civilised society and that it is the product of too much social care. Nothing could be more absurd, since the group is, by its nature and by definition looked after inadequately.

From the point of view of the biologist, this group is "fit" because it has a high fertility, though from the ordinary social point of view the members are "unfit". Actually, its separation from the rest of the community is arbitrary, and implies an assumption similar to that made a century ago by students of criminality and sponsored by Lombroso (1887). The subcultural, or social problem, human being has separate existence no more than the criminal type. Poor physique, criminality, inferior intellectual stature, and low economic status can easily be shown to be correlated, but the causes of the associations are not simple (Goring 1913). We must beware of assuming that the social-problem group exists because it has a name. For the purpose of discussing biological fitness, however, it may be convenient to assume its existence even if this involves considerable over simplification.

FERTILITY AND INTELLIGENCE

Lately much attention has been given to the problem of the general intelligence level in the population. The relatively high fertility prevalent in the social problem group is thought to imply that its numbers will increase to the detriment of the rest of the community. As I have previously often pointed out, such predictions are based upon particular assumptions about the genetical structure of the population, and there are important possibilities which have been overlooked. To get a clear picture, we must first of all examine the relation of fertility to intelligence over the whole range of values—that is to say, from the most brilliant to the dullest, even including idiots.

All investigators agree that the fertility of the most intelligent is low, and that, within most of the normal range, fertility rises steadily as intelligence quotient (I.Q.) falls. Idiots, however, are infertile even if they survive infancy, so, at some point in the scale of I.Q., fertility must reach a maximum. The net fertility of persons with intellects of very low grade has not been at all fully investigated. A good way of examining the problem would be to compare the intelligence distribution of the population at birth with the distribution of intelligence among the parents of every child born. Parents of two children would be represented twice in the sample and parents of three children three times and so on.

* A paper read to the North West Metropolitan Regional Mental Deficiency Society, on Feb 27 1950

The result of such a survey would reveal the representation of each level in the parental generation and enable relative fertility to be directly calculated. A near approach to data of this kind can be obtained by comparing the parents and sibs of the defectives surveyed at Colchester (Penrose 1938). This population, on which the figures in table I are based, is selected by the presence of at least one mentally defective child in each sibship, but it is useful for demonstration purposes. Estimates of the relative fertility are probably quite good for the lower levels of I Q but would be inaccurate at the upper levels, which are not well represented in the sample. It is immediately apparent that, for both sexes, there is a maximal fertility at some point between I Q 50 and I Q 100. Furthermore, the females and males differ strongly in this respect. Feeble minded females are far more biologically fit than feeble minded males—i.e., about three times as fertile. The same is true for imbeciles, and this method of demonstration agrees with what is known from direct observation. Idiots of both sexes are completely infertile.

The problem of segregating a patient because of the danger of offspring arises far more often with females than with males. There are even records of female phenylketonurics and mongols having had offspring, but no such examples in males. This may be partly due to the difficulty of knowing when a male imbecile has had a child, but the sex difference is probably real. Mating with respect to I Q is highly assortative, in that the intelligent and the unintelligent do not mix as much as would be expected by chance. The assortment, however, is asymmetrical because matings between the intelligent male and the unintelligent female are much commoner than those of the reverse type. This is probably a constant sociobiological fact.

The remarkable feature, shown in table I, that the relative fertility at both the extremes is reduced, can be expressed by saying that the range of variation with respect to intelligence is greater in the offspring than in the parents. Variation expressed as standard deviation is shown, in table II, to be 17.64 I Q points for all offspring and only 13.71 for all parents. A similar effect is shown

TABLE I—PERCENTAGE DISTRIBUTIONS OF PARENTS AND SIBS OF CERTIFIED CASES OF MENTAL DEFECT

I Q	Fathers (1214)	Sons (2357)	Fertility*	Mothers (1251)	Daughters (2288)	Fertility*
122	0.7	1.4	0.50	0.2	1.6	0.13
100	83.0	79.4	1.04	72.0	77.5	0.93

* Fertility = relative fertility (% parents/% children)

in the analysis of some metrical physical characters. For example, the calculations of Pearson and Lee (1896) show that stature is slightly more variable in offspring than in parents. Cephalic index shows the same peculiarity quite strongly, both in the material analysed by Pearson and Fawcett (1898) and (according to calculations made recently in the Galton Laboratory) in the extensive data of Frets (1924). The mean values for parents and offspring differ slightly, but this does not necessarily imply that the population mean is gradually shifting. The difference could be caused by recessivity of some of the genes involved. Thus, the slightly lower mean I Q in children compared with their parents could be due to recessive types of imbecility and idiocy, many of which are actually known to exist.

In general, a greater variance in each generation of offspring as compared with parents indicates that the population is being replenished from the middle of

TABLE II—MEANS AND STANDARD DEVIATIONS IN PARENTS AND OFFSPRING

S D = standard deviation

the range. If the hereditary factors which contribute to the variation are mainly additive, the central part of the distribution must be, on the whole, heterozygous for the genes concerned, whereas the extremes are homozygous. Thus, the population is being bred chiefly from heterozygotes. Biologically, a population propagated in this way has certain advantages. Variability is permanently retained and the genetic equilibrium is stable. The relative infertility of those who have very high intelligence is compensated biologically by the complete infertility of those of the lowest intellectual levels, and a progressive decline in the average level is not to be expected. Both ends of the scale are replenished by a fertile intermediate group.

CAUSES AND EFFECTS OF DIFFERENTIAL FERTILITY

The causes of differential fertility with respect to intelligence are not altogether clear at the present time. They are partly physiological and partly psychological. It is believed that there are many environmental factors which influence fertility, such as malnutrition (Swyer 1948) and disease. Apart from these influences, there are likely to be inborn differences in potential fertility, which are expressed sometimes in structure and sometimes in reaction patterns. The comparative infertility of men of genius, which was noted by Galton (1869), may be mainly a psychological phenomenon like the celibacy of the learned in the Middle Ages. Demographers of the present day have stressed the cultural origins of differential fertility, which again implies a psychological origin. Cultural habits, also, tend to reduce the fertility of highly intellectual women even more than that of men of similar level. It is also worthy of note that the risks of maternity are greater, as judged by mortality statistics, for the women of the most favoured social classes—who may have been regarded as especially well endowed intellectually—than for women of the least favoured social groups. At the lower end of the scale, the infertility of imbeciles is largely due to psychological causes. The evidence for physiological sexual incapacity in low grade defectives is surprisingly small. Among females of medium and high grades, investigations on the menstrual function have shown little if any deviation from the normal (Danehower 1948).

It may be, I think, not unreasonably concluded that the system of differential fertility found in civilised populations is a naturally balanced one and that there is no need to fear the effects of high fertility in the lower social and intellectual groups. In so far as intelligence is environmentally determined, the mental level of the parents is biologically immaterial in the long run, though, for the immediate offspring, environment simulating heredity may depend on the parents' intelligence.

Thus it seems to follow that, whether we regard intelligence as inherited or environmentally determined, the judgment of suitability of an individual for parenthood should be based frankly upon social rather than upon genetical considerations. If the patient is biologically fit, his or her children will take their places in the genetic equilibrium of the whole population. It may however be desirable on clinical or social grounds

to restrict such a person's offspring, that is to say, parenthood, in a given case, might cause mental breakdown of the patient or alternatively produce an unhealthy environment for the child. These are problems which are concrete and within the scope of clinical and social medicine. If judgment is based on these grounds, no eugenic harm will be done and uncertainties inherent in making genetical estimates will be avoided.

The principle recommended here is parallel to one of the suggestions in the Brock report (1934)—namely, that defectives who are totally unfitted for parenthood should, in their own interests, be enabled to escape from a burden they have every reason to dread. But in other respects the views expressed here differ from those expressed in the Brock report, for I do not think that the "mass of defectives and subnormals" is steadily growing. The genetical constitution of future generations is not, I believe, likely to be jeopardised by allowing fertile high-grade defectives to have offspring. Propagation of the unfit is not a danger to the community, because the unfit are those who cannot propagate.

SUMMARY

Decisions about segregation or otherwise of high grade patients should be based solely on medical, psychological, and social grounds and the future population can be trusted to retain its equilibrium with respect both to biological fitness and intelligence level.

From the Department of Bacteriology Trinity College Dublin

The action of sulphathiazole on *Bacterium coli* in fluid culture media was studied in connection with an investigation of the synergism and antagonism of certain antibacterial substances (Bigger 1950). In the course of the work a hitherto undescribed phenomenon was encountered which is now reported here.

TECHNIQUE

A single strain of *Bact. coli* was used throughout the research.

Sulphathiazole (M & B) was dissolved in distilled water with the aid of sodium hydroxide to make a 5% stock solution of pH 10.0 which was sterilised by boiling. Enough of the stock solution was then added to a fluid culture medium in screw top bottles to produce the required concentration of sulphathiazole. The

pH was adjusted to 7.5, and the medium was sterilised in boiling water for 15 minutes, after which the pH was tested and if necessary readjusted to 7.5. The highest concentration of sulphathiazole attainable without risk of precipitation was somewhat below 300 mg per 100 ml. The highest concentration used was 256 mg per 100 ml.

Sulphathiazole solutions in a culture medium were serially diluted in 5 ml volumes of the same medium in small bottles covered with loosely fitting aluminium caps. The bottles were inoculated by adding to each one drop from a Drever pipette of a suitable dilution of a 24-hour culture of the organism grown in a fluid medium. The bottles were incubated at 37°C and examined daily for two or three days. The naked eye appearance of the medium was recorded as C (clear), T (slight to moderate turbidity), or TT (well marked to full turbidity).

A 5 mm loopful from each culture which had remained clear was spread over the surface of a well-dried agar slope containing 0.5% *p*-aminobenzoic acid to prevent the sulphathiazole from interfering with the growth of organisms. The slopes were incubated and the resulting colonies counted. It was possible to count up to several hundred colonies on a slope with reasonable accuracy. When the number was too great to be counted the growth was recorded as — (colonies uncountable) or —+ (confluent growth).

ACTION OF SULPHATHIAZOLE IN BROTH

The well known sulphonamide antagonising action of broth rendered it unsuitable as a culture medium for this research. Treatment by the method of Harper and Cawston (1945) decreased, but did not abolish, this property, and, in our hands, did not give uniform results with different batches of broth and of horse blood.

Table 1 compares the results obtained in a parallel titration of sulphathiazole acting against *Bact. coli* in plain broth and in broth treated by the method of Harper and Cawston. In plain broth sulphathiazole displayed merely a bacteriostatic—i.e., growth restraining (Bigger 1950)—action against the organism in the highest concentrations tested and no apparent action in concentrations of 64 mg per 100 ml and lower. In treated broth one-loop sterility was yielded by concentrations of sulphathiazole of 64 mg per 100 ml and higher and a bacteriostatic effect was obtained with concentrations as low as 4 mg per 100 ml.

ACTION OF SULPHATHIAZOLE IN SYNTHETIC MEDIA

Bact. coli was selected as the test organism because it grows well in simple synthetic media which are less actively sulphonamide antagonising than broth. The first medium tried was one whose formula is given by Gale (1947). In this medium sulphathiazole displayed both bactericidal and bacteriostatic properties in very

The result of such a survey would reveal the representation of each level in the parental generation and enable relative fertility to be directly calculated. A near approach to data of this kind can be obtained by comparing the parents and sibs of the defectives surveyed at Colchester (Penrose 1938). This population, on which the figures in table I are based, is selected by the presence of at least one mentally defective child in each sibship, but it is useful for demonstration purposes. Estimates of the relative fertility are probably quite good for the lower levels of *i* *q* but would be inaccurate at the upper levels, which are not well represented in the sample. It is immediately apparent that, for both sexes, there is a maximal fertility at some point between *i* *q* 50 and *i* *q* 100. Furthermore, the females and males differ strongly in this respect. Feeble minded females are far more biologically fit than feeble minded males—i.e., about three times as fertile. The same is true for imbeciles, and this method of demonstration agrees with what is known from direct observation. Idiots of both sexes are completely infertile.

The problem of segregating a patient because of the danger of offspring arises far more often with females than with males. There are even records of female phenylketonurics and mongols having had offspring, but no such examples in males. This may be partly due to the difficulty of knowing when a male imbecile has had a child, but the sex difference is probably real. Mating with respect to *i* *q* is highly assortative, in that the intelligent and the unintelligent do not mix as much as would be expected by chance. The assortment, however, is asymmetrical because matings between the intelligent male and the unintelligent female are much commoner than those of the reverse type. This is probably a constant sociobiological fact.

The remarkable feature, shown in table I, that the relative fertility at both the extremes is reduced, can be expressed by saying that the range of variation with respect to intelligence is greater in the offspring than in the parents. Variation expressed as standard deviation is shown, in table II, to be 17.64 *i* *q* points for all offspring and only 13.71 for all parents. A similar effect is shown

the range. If the hereditary factors which contribute to the variation are mainly additive, the central part of the distribution must be, on the whole, heterozygous for the genes concerned, whereas the extremes are homozygous. Thus, the population is being bred chiefly from heterozygotes. Biologically, a population propagated in this way has certain advantages. Variability is permanently retained and the genetic equilibrium is stable. The relative infertility of those who have very high intelligence is compensated biologically by the complete infertility of those of the lowest intellectual levels, and a progressive decline in the average level is not to be expected. Both ends of the scale are replenished by a fertile intermediate group.

CAUSES AND EFFECTS OF DIFFERENTIAL FERTILITY

The causes of differential fertility with respect to intelligence are not altogether clear at the present time. They are partly physiological and partly psychological. It is believed that there are many environmental factors which influence fertility, such as malnutrition (Sverre 1948) and disease. Apart from these influences, there are likely to be inborn differences in potential fertility, which are expressed sometimes in structure and sometimes in reaction patterns. The comparative infertility of men of genius, which was noted by Galton (1869), may be mainly a psychological phenomenon like the celibacy of the learned in the Middle Ages. Demographers of the present day have stressed the cultural origins of differential fertility, which again implies a psychological origin. Cultural habits, also, tend to reduce the fertility of highly intellectual women even more than that of men of similar level. It is also worthy of note that the risks of maternity are greater, as judged by mortality statistics, for the women of the most favoured social classes—who may have been regarded as especially well endowed intellectually—than for women of the least favoured social groups. At the lower end of the scale, the infertility of imbeciles is largely due to psychological causes. The evidence for physiological sexual incapacity in low grade defectives is surprisingly small. Among females of medium and high grades, investigations on the menstrual function have shown little if any deviation from the normal (Danehower 1948).

It may be, I think, not unreasonably concluded that the system of differential fertility found in civilized populations is a naturally balanced one and that there is no need to fear the effects of high fertility in the lower social and intellectual groups. In so far as intelligence is environmentally determined, the mental level of the parents is biologically immaterial in the long run, though, for the immediate offspring, environment simulating heredity may depend on the parents' intelligence.

Thus it seems to follow that, whether we regard intelligence as inherited or environmentally determined, the judgment of suitability of an individual for parent hood should be based frankly upon social rather than upon genetic considerations. If the patient is biologically fit, his or her children will take their places in the genetic equilibrium of the whole population. It may however be desirable on clinical or social grounds

INVESTIGATION

Effect of Broth

Sulphathiazole was titrated in S.M. in duplicate. To the bottles in one set (containing 5 ml. of S.M.) a drop of broth was added, so giving approximately 1% broth, to those in the other set no broth was added. Both sets were inoculated with a dilution of a culture of the organism in saline solution. The results are given in table III. In the series without broth there was no paradoxical result, and turbidity first appeared in the bottle containing $\frac{1}{32}$ mg. of sulphathiazole per 100 ml. In the series to which broth had been added a paradoxical result was given by the first and second bottles, and turbidity developed in the bottle containing 1 mg. sulphathiazole per 100 ml.

Effects of Lemco and Peptone

Since the broth had been prepared from 'Lab-Lemco' and Parke Davis peptone, the next step was to investigate the effects of lemco and peptone separately and together. Table IV shows the results obtained in the crucial experiment of the research. Sulphathiazole was titrated against *Bact. coli* in S.M. alone and in S.M. to which had been added 1 5000 peptone, 1 5000 lemco, and 1 5000 peptone plus 1 5000 lemco. No concentration of

sulphathiazole tested in S.M. alone reduced the one loop count to zero in 48 hours, whereas in the presence of peptone the counts were considerably higher, and the presence of lemco yielded zero counts with each concentration of sulphathiazole tested. When both peptone and lemco were present, lemco seemed to neutralise considerably the antagonising action of peptone on sulphathiazole in concentrations ranging from 64 to 4 mg. per 100 ml. The most striking finding in this experiment was the acceleration in the rate of death of the bacteria in the presence of lab lemco.

Table V gives a more complete comparison of the effects of sulphathiazole on *Bact. coli* in S.M. alone and with the addition of 1 20,000 lab lemco (L.S.M.)

In some comparisons of S.M. and L.S.M. the presence of lemco slightly extended the power of sulphathiazole to prevent the development of turbidity, but the most constant result of the presence of lemco was great acceleration of the rate of death of the bacteria in the presence of sulphathiazole. "L effect" has been adopted as a convenient name for this property of lemco, and "L substance" for the constituent of lemco responsible for the effect.

We have already expressed some doubt as to whether, when acting in S.M., sulphathiazole could properly be described as bactericidal. In the presence of lemco, however, it certainly is bactericidal. Since lemco is not an antibacterial substance, the term "synergistic"

cannot be applied to it in relation to sulphathiazole if we accept the definition adopted by Bigger (1950). We suggest "potentiation" as more appropriate, for lemco certainly gives power to sulphathiazole—power to kill rather than to restrain the multiplication of bacteria.

The L effect was demonstrated in lemco over a wide range of concentrations. The lowest effective concentration varied with different batches of lemco and, to some extent, from experiment to experiment performed with the same batch. In many experiments lemco was still active as a potentiator of sulphathiazole when present in S.M. in a concentration of 1 120,000. When lemco was present in high concentrations—e.g., 1 100 and occasionally even 1 1000—it did not accelerate the rate of killing of bacteria and seemed to act antagonistically to sulphathiazole. This is attributed to the presence in lemco of sulphonamide antagonising substances which are diluted to below their effective concentration earlier than the L substance. For this and other reasons a concentration of 1 part of lab lemco to 20,000 parts of S.M. was considered optimal, and this concentration was invariably used in making L.S.M.

Test for L effect

The next step was to determine whether the L effect could be demonstrated in substances other than lab lemco. A satisfactory technique for the purpose was devised and was used in all such tests. The substance under test was serially diluted in S.M. containing 16 mg. of sulphathiazole per 100 ml. The controls consisted of three bottles containing 16 mg. of sulphathiazole per 100 ml. in S.M. and three containing the same concentration of sulphathiazole in L.S.M. All were inoculated, incubated, and tested in the usual way. The criterion on which reliance was placed for determining whether a substance in a particular concentration displayed the

much lower concentrations than it did in Harper and Crivston broth

In the earlier experiments the cultures for inoculation were grown in broth. Later, since it was considered that some error might be introduced by transferring bacteria from broth to a synthetic medium which, obviously, calls into play a variety of enzymes not required in broth, they were grown in synthetic medium. We were long harassed by uncertainty as to the number of bacteria in the inoculum. We always added one drop of what was considered a suitable dilution of the culture in synthetic medium to each 5 ml. of the test fluid, and hoped that this fluid would then contain such a number of bacteria as to yield about 25 colonies from one 5 mm loopful. Over some months this aim was rarely achieved. The addition to 5 ml of culture medium of one drop of a 1:2000 dilution of an approximately 24 hour culture in Gale's medium of the same strain of *Bact. coli* yielded 2-75 colonies per loop. Several experiments had to be abandoned because the inoculum had contained either too many or too few living bacteria. After much time had been wasted, we began to suspect that Gale's medium was not so suitable for our purpose as we had thought. Investigation showed that, if the period of incubation was not more than 18-20 hours, it was possible to predict with considerable accuracy the number of living bacteria present, but, if incubation was longer, the number of living bacteria fell rapidly. This was due to the development of such a high degree of acidity as to cause the death of most of the bacteria present. A pH as low as 4.7 was found in a 26 hour culture, and at this pH *Bact. coli* dies rapidly. The low pH attained was due to an excess of glucose and a deficiency of phosphates in the medium.

Ultimately a medium with the following formula was adopted and used throughout the rest of the investigation.

Synthetic Medium (S M)

Glucose	30 g
Ammonium hydrogen phosphate ((NH ₄) ₂ HPO ₄ · 2H ₂ O)	50 g
Sodium chloride (NaCl)	10 g
Ferrous sulphate (FeSO ₄ · 7H ₂ O)	0.3 g
Magnesium sulphate (MgSO ₄ · 7H ₂ O)	0.7 g
Potassium hydrogen phosphate (KH ₂ PO ₄)	0.5 g
Potassium hydrogen phosphate (K ₂ HPO ₄)	50 g
Water to	1000 ml

pH adjusted to 7.5

The pH of a culture of *Bact. coli* in this medium after 30 hours' incubation was 6.6, which is not rapidly lethal to the organism.

As a result of the precipitation of phosphates during sterilisation by heat, the concentrations of iron, magnesium, and phosphate in the medium used are considerably lower than stated in the formula. The medium could be improved, and the necessity for filtration almost or completely avoided, by a great reduction in the concentrations of ferrous and magnesium sulphates, but, as this was not investigated until much of the work had been done, the formula given was used throughout.

Table II shows the mean of the figures obtained in four parallel titrations of sulphathiazole against *Bact. coli* in S M. Turbidity did not appear until the concentration of sulphathiazole had been reduced to 1/4 mg per 100 ml, which contrasts with turbidity in the presence of 4 mg sulphathiazole per 100 ml in Harper and Crivston broth. *Bact. coli* is very sensitive to sulphathiazole when no antagonising substances are present.

Attention is directed particularly to two points. First, not even the highest concentration of sulphathiazole yielded a zero count per loopful in 48 hours. The time

required to produce zero counts varied greatly in different experiments. They were never obtained in S M in 24 hours, and very rarely in 48 hours. When incubation was greatly prolonged, zero counts were normally obtained with all concentrations down to 1/4 mg per 100 ml. In view of the long period required to reduce the bacterial population to zero, we are entitled to doubt if sulphathiazole is to be regarded as a bactericidal substance. It might be thought, rather fancifully perhaps, that the bacteria, tired of their struggle against the bacteriostatic influence of sulphathiazole, had died, rather than that they had been killed by the substance. The second point to which attention is called is that the 48 hour count with the highest concentration of sulphathiazole was higher than with lower concentrations. This paradoxical result has appeared so frequently, although not constantly, that it must be accepted as valid.

EFFECT OF DILUENT

So far no mention has been made of the fluid used for diluting a culture of the organism intended for inoculation. In the earlier part of the investigation this was physiological saline solution to which a "little" broth had been added. Such an unscientific terminology is used deliberately because the addition was made casually by pouring some broth into a tube containing sterile saline. In most cases the proportion of broth to saline probably lay between 1:5 and 1:10. Broth saline was used instead of plain saline because, many years ago, working with *Staph. pyogenes*, one of us (J W B) found that, if a culture of that organism was diluted in plain saline solution, the bacteria died quite rapidly, whereas their numbers remained constant for a long time if they were diluted in saline solution containing broth. Since then the practice of diluting cultures in broth saline has been adopted almost automatically.

One day one of us and a colleague independently made titrations of sulphathiazole in S M. The same solution of sulphathiazole, the same batch of S M, and the same culture were used, and the work was done at about the same time. The first bottle in the series to show turbidity was that containing 1/4 mg of sulphathiazole per 100 ml in one titration, and that containing 1/32 mg of sulphathiazole per 100 ml in the second titration. Such a degree of disparity could not fail to be distasteful to workers who take pride in their technique, and so the technical details were fully discussed. As a result only one possibly significant difference was discovered: the worker who obtained the higher titre, not having experienced the lethal effect of plain saline on bacterial suspensions, had used plain saline as diluent, whereas the other worker had used broth saline. It therefore seemed advisable to investigate the effect of the addition of broth to S M.

INVESTIGATION

Effect of Broth

Sulphathiazole was titrated in s.m. in duplicate. To the bottles in one set (containing 5 ml of s.m.) a drop of broth was added, so giving approximately 1% broth, to those in the other set no broth was added. Both sets were inoculated with a dilution of a culture of the organism in saline solution. The results are given in table III. In the series without broth there was no paradoxical result, and turbidity first appeared in the bottle containing $\frac{1}{32}$ mg of sulphathiazole per 100 ml. In the series to which broth had been added a paradoxical result was given by the first and second bottles, and turbidity developed in the bottle containing 1 mg sulphathiazole per 100 ml.

Effects of Lemco and Peptone

Since the broth had been prepared from 'Lab-Lemco' and Parke Davis peptone, the next step was to investigate the effects of lemco and peptone separately and together. Table IV shows the results obtained in the crucial experiment of the research. Sulphathiazole was titrated against *Bact. coli* in s.m. alone and in s.m. to which had been added 1 5000 peptone, 1 5000 lemco, and 1 5000 peptone plus 1 5000 lemco. No concentration of

sulphathiazole tested in s.m. alone reduced the one loop count to zero in 48 hours, whereas in the presence of peptone the counts were considerably higher, and the presence of lemco yielded zero counts with each concentration of sulphathiazole tested. When both peptone and lemco were present, lemco seemed to neutralise considerably the antagonising action of peptone on sulphathiazole in concentrations ranging from 64 to 4 mg per 100 ml. The most striking finding in this experiment was the acceleration in the rate of death of the bacteria in the presence of lab lemco.

Table V gives a more complete comparison of the effects of sulphathiazole on *Bact. coli* in s.m. alone and with the addition of 1 20,000 lab lemco (L.S.M.).

In some comparisons of s.m. and L.S.M. the presence of lemco slightly extended the power of sulphathiazole to prevent the development of turbidity, but the most constant result of the presence of lemco was great acceleration of the rate of death of the bacteria in the presence of sulphathiazole. 'L effect' has been adopted as a convenient name for this property of lemco and 'L substance' for the constituent of lemco responsible for the effect.

We have already expressed some doubt as to whether, when acting in s.m., sulphathiazole could properly be described as bactericidal. In the presence of lemco, however, it certainly is bactericidal. Since lemco is not an antibacterial substance, the term 'synergistic'

cannot be applied to it in relation to sulphathiazole if we accept the definition adopted by Bigger (1950). We suggest 'potentiation' as more appropriate, for lemco certainly gives power to sulphathiazole—power to kill rather than to restrain the multiplication of bacteria.

The L effect was demonstrated in lemco over a wide range of concentrations. The lowest effective concentration varied with different batches of lemco and, to some extent, from experiment to experiment performed with the same batch. In many experiments lemco was still active as a potentiator of sulphathiazole when present in s.m. in a concentration of 1 120,000. When lemco was present in high concentrations—e.g., 1 100 and occasionally even 1 1000—it did not accelerate the rate of killing of bacteria and seemed to act antagonistically to sulphathiazole. This is attributed to the presence in lemco of sulphonamide antagonising substances which are diluted to below their effective concentration earlier than the L substance. For this and other reasons a concentration of 1 part of lab lemco to 20,000 parts of s.m. was considered optimal and this concentration was invariably used in making L.S.M..

Test for L effect

The next step was to determine whether the L effect could be demonstrated in substances other than lab-lemco. A satisfactory technique for the purpose was devised and was used in all such tests. The substance under test was serially diluted in s.m. containing 16 mg of sulphathiazole per 100 ml. The controls consisted of three bottles containing 16 mg of sulphathiazole per 100 ml in s.m. and three containing the same concentration of sulphathiazole in L.S.M. All were inoculated, incubated, and tested in the usual way. The criterion on which reliance was placed for determining whether a substance in a particular concentration displayed the

L effect was that it should give a zero colony count, while the counts given by the controls containing sulphathiazole in S.M. were not less than the initial count. The period of incubation was 30–48 hours. If the period was too short (e.g., 24 hours), the L.S.M. controls did not always give zero counts, if too long (e.g., over 48 hours) some of the S.M. controls did occasionally give zero counts. Table VI, which gives the results obtained in testing 'Brand's Essence' for L effect, illustrates the method. The controls, which show high counts in S.M. and zero counts in L.S.M., being satisfactory, we may conclude that Brand's essence displayed the L effect in dilutions up to 1 3200.

Effect of Other Substances

The L effect was demonstrated by this method not only by lab. lemco and Brand's essence but also by other commercial meat extracts ('Lemco,' 'Oxo,' and 'Ernox'), by infusions of beef, 'Difco' dehydrated beef and horseflesh, by commercial yeast extracts ('Marmite' and 'Gye'), by human serum and urine, and by hemolysed red blood cells. Of these, gye (Guinness's yeast extract) was the most potent, showing in some experiments the L effect in a dilution of 1 320,000. The range displayed by different samples of human serum was from 1 1000 to 1 2000, and of human urine from 1 2000 to 1 6000. Hemolysed human red blood-cells showed the L effect up to a dilution of 1 800, and horse red blood cells at 1 50, but not at 1 100. In the case of blood cells the titre is expressed in terms of packed cells. All the substances mentioned had been exposed to a temperature of at least 100°C for not less than 15 minutes before being tested.

Effect on Other Sulphonamides

The L effect was studied almost entirely in connection with sulphathiazole, but sufficient work was done to establish that it operated similarly in the case of other sulphonamides, including sulphanilamide, sulphapyridine, sulphaguanidine, sulphadiazine, sulphamerazine, and phthalylsulphathiazole and (to a lower extent) succinyl sulphathiazole.

Effect on Other Antibacterial Substances

The addition of lemco to S.M. had an almost negligible effect on the action of penicillin, streptomycin, chloramphenicol, and boric acid. This was not true, however, of the sodium salt of *p* aminosalicylic acid (P.A.S.). It is not proposed to consider in detail the effect of lemco on P.A.S., but it may be stated that, whereas lemco increases the rapidity of the bactericidal action of sulphathiazole

on *Bact. coli* without altering its bacteriostatic titre, its main action on P.A.S. is greatly to extend the bacteriostatic titre of the substance without appreciably altering its bactericidal effect.

ACTION OF SULPHATHIAZOLE IN S.M. AND IN L.S.M.

In most of the experiments counts were made after about 24, 48, and 72 hours' incubation. It seemed desirable to supplement the information so obtained by making counts at intervals of 2 or 4 hours. It will suffice to give details of one such experiment, the results of which were in general agreement with those obtained in other experiments. To avoid the use of large numbers of bottles and slopes, only two concentrations of sulphathiazole (64 and 4 mg. per 100 ml.) in S.M. and L.S.M. were used. The figures in table VII, which were used for the construction of figs. 1 and 2, were the means of the counts obtained in three similar bottles in each case.

First we may compare the counts obtained with a concentration of 64 mg. of sulphathiazole per 100 ml. in S.M. and in L.S.M. (fig. 1). In S.M., after a small initial fall, the number of living bacteria increased slowly to a peak, at 10 hours, of just over three times the initial number. Thereafter the number fell slowly and somewhat irregularly. At 48 hours the number was identical with the initial number, at 60 hours slightly lower, and at 100 hours zero. The corresponding counts obtained with L.S.M. are completely different. The number rose steeply to a peak of ten times the initial number at 8 hours, fell equally steeply to below the initial number at 16 hours, and then fell more slowly, reaching zero at 24 hours.

The curve given by 4 mg. sulphathiazole per 100 ml. in S.M. differed markedly from that obtained with the higher concentration in the same medium. Three peaks, each followed by a fall, occurred within the first 36 hours. The primary peak was the highest (twenty two times the initial number), the secondary and tertiary peaks being identical at fourteen times the initial number. Following the third peak there was a very slow fall to slightly below the initial number at 100 hours and to zero at 312 hours. The curve given by the same concentration of sulphathiazole in L.S.M. presents a complete contrast. The two curves are almost identical up to 6 hours, but in L.S.M. the peak (twelve times the initial number) was reached at that time and the count then fell sharply to below the initial count at 16 hours and to zero at 24 hours.

The following generalisations appear to be legitimate

- (1) Sulphathiazole in a high concentration in S.M. is so bacteriostatic as almost to justify the use of the term bacteriostatic. Several days are required before sterility is reached.
- (2) Sulphathiazole in a low concentration (such as is attainable in the human body) in S.M. allows considerable multiplication of the bacteria before bacteriostatic action appears. A very much longer time is required for the production of sterility than is the case with high concentrations.
- (3) In the presence of lemco, high and low concentrations of sulphathiazole give almost identical results, which are completely different from those given by the same concentrations when lemco is absent. After a short period of multiplication of the bacteria the count falls to zero so rapidly as to justify the application of the term bactericidal to the action of sulphathiazole.

MODE OF ACTION OF LEMCO

In an attempt to throw light on the mode of action of lemco the rate of multiplication of *Bact. coli* in S.M. and in L.S.M. without sulphonamide was investigated in several experiments. Since the results obtained in these experiments were essentially similar, an account of one of them will suffice. Two bottles containing S.M. and two containing L.S.M. were inoculated with *Bact. coli* and incubated. Counts were made at 2 hour intervals up to 14 hours. The figures given in table VIII are the means of the counts obtained in the pairs of bottles.

Lemco (this is not necessarily true of L substance) stimulates the growth of *Bact. coli* in S.M. Up to 4 hours its action is scarcely detectable, at 6 hours obvious although slight, and at 8 hours definite. Anything increasing the rate of multiplication of a bacterium might assist the antibacterial action of a substance such as sulphathiazole, and the possibility that L substance acts in this way must be considered. Even if pure L substance behaves as did lemco in this experiment, it may be asserted with considerable confidence that it is not because of its growth stimulating action that L substance potentiates sulphathiazole. The reason for this assertion is that this action of lemco is not clearly demonstrable until after 4 hours' incubation, whereas, as is seen in table VII and fig. 1, the effect of lemco in the

TABLE VIII—EFFECT OF LEMCO ON RATE OF MULTIPLICATION OF *Bact. coli*

Hours	No. of bacteria per loop

4	210	230
6	400	600
8	+ / + +	+ +
10	+ + +	+ +
12	C (T)	T
14	T	TT

presence of sulphathiazole is obvious after 2 hours' incubation and striking after 4 hours.

None of the experiments to elucidate the mode of action of the combination of L substance and sulphathiazole has thrown any light on the problem, and in the absence of experimental evidence mere speculation would be valueless. It is not therefore proposed at present to propound any explanation of the L effect.

EXPERIMENTS WITH URINE

Experiments were made in which human urine and human serum, in both of which *Bact. coli* grows well, were used as culture media.

The pH of one portion of a sample of urine was adjusted to 7.5, and the urine was boiled, the precipitated phosphates being removed by centrifuging. Another portion of the same sample of urine was treated by contact with a synthetic resin which was known to adsorb L substance from fluids containing it. The pH was adjusted and the phosphates were removed as in the case of the first portion. Sulphathiazole was added to both untreated and treated urines so as to give a concentration of 64 mg per 100 ml, a concentration usually attained and often exceeded in the urine of a patient undergoing treatment. The two samples of urine were inoculated with *Bact. coli* (22 per loop) and examined after 24 hours' incubation. The count in the untreated urine was 0, and in the treated urine 25. Urine, therefore, in the presence of sulphathiazole, displays the L effect and can be deprived of this property by contact with a material which adsorbs L substance. Attempts to restore L activity to treated urine by the addition of lemco were only partially successful.

EXPERIMENTS WITH SERUM

Fresh human serum to which had been added sulphathiazole to give a concentration of 8 mg per 100 ml, a concentration easily attainable in the blood of a patient, was inoculated, incubated, and tested. An initial count of 22 was reduced to zero in 24 hours. Serum, therefore, like urine, displays the L effect, but it was impossible to remove the L substance from it owing to alterations consequent on the great reduction in pH produced by contact with the synthetic resin.

These experiments with urine and serum go further than the demonstration, already mentioned, that the addition of either urine or serum to synthetic medium containing sulphathiazole produces the L effect. In these experiments the body fluids (one heated, the other unheated) themselves acted as culture media and, in conjunction with sulphathiazole, displayed the L effect. It is impossible to state definitely that the substance in them responsible for the rapid killing of bacteria by sulphathiazole is identical with the L substance present in lemco, but it certainly behaves in the same way.

IDENTITY OF L SUBSTANCE

The final experiments were undertaken in an attempt to determine whether the L substance was the same as the potentiator of sulphonamide activity present in

Fig. 1—Comparison of effects of sulphathiazole 64 mg per 100 ml in S.M. and in L.S.M.

Fig. 2—Comparison of effects of sulphathiazole 4 mg per 100 ml in S.M. and in L.S.M.

L effect was that it should give a zero colony count, while the counts given by the controls containing sulphathiazole in S.M. were not less than the initial count. The period of incubation was 30–48 hours. If the period was too short (e.g., 24 hours), the L.S.M. controls did not always give zero counts, if too long (e.g., over 48 hours) some of the S.M. controls did occasionally give zero counts. Table VI, which gives the results obtained in testing 'Brand's Essence' for L effect, illustrates the method. The controls, which show high counts in S.M. and zero counts in L.S.M., being satisfactory, we may conclude that Brand's essence displayed the L effect in dilutions up to 1 3200.

Effect of Other Substances

The L effect was demonstrated by this method not only by lab. lemco and Brand's essence but also by other commercial meat extracts ('Lemco,' 'Oxo,' and 'Erinox'), by infusions of beef, 'Difco' dehydrated beef and horseflesh, by commercial yeast extracts ('Marmite' and 'Gye'), by human serum and urine, and by hæmolyzed red blood cells. Of these, gye (Gunn's yeast extract) was the most potent, showing in some experiments the L effect in a dilution of 1 320,000. The range displayed by different samples of human serum was from 1 1000 to 1 2000, and of human urine from 1 2000 to 1 6000. Hæmolyzed human red blood cells showed the L effect up to a dilution of 1 800, and horse red blood cells at 1 50, but not at 1 100. In the case of blood cells the titre is expressed in terms of packed cells. All the substances mentioned had been exposed to a temperature of at least 100°C for not less than 15 minutes before being tested.

Effect on Other Sulphonamides

The L effect was studied almost entirely in connection with sulphathiazole, but sufficient work was done to establish that it operated similarly in the case of other sulphonamides, including sulphanilamide, sulphapyridine, sulphaguanidine, sulphadiazine, sulphamerazine, and phthalylsulphathiazole and (to a lower extent) succinylsulphathiazole.

Effect on Other Antibacterial Substances

The addition of lemco to S.M. had an almost negligible effect on the action of penicillin, streptomycin, chloramphenicol, and boric acid. This was not true, however, of the sodium salt of *p*-aminosalicylic acid (P.A.S.). It is not proposed to consider in detail the effect of lemco on P.A.S., but it may be stated that, whereas lemco increases the rapidity of the bactericidal action of sulphathiazole

on *Bact. coli* without altering its bacteriostatic titre, its main action on P.A.S. is greatly to extend the bacteriostatic titre of the substance without appreciably altering its bactericidal effect.

ACTION OF SULPHATHIAZOLE IN S.M. AND IN L.S.M.

In most of the experiments counts were made after about 24, 48, and 72 hours' incubation. It seemed desirable to supplement the information so obtained by making counts at intervals of 2 or 4 hours. It will suffice to give details of one such experiment, the results of which were in general agreement with those obtained in other experiments. To avoid the use of large numbers of bottles and slopes, only two concentrations of sulphathiazole (64 and 4 mg per 100 ml) in S.M. and L.S.M. were used. The figures in table VII, which were used for the construction of figs 1 and 2, were the means of the counts obtained in three similar bottles in each case.

First we may compare the counts obtained with a concentration of 64 mg of sulphathiazole per 100 ml in S.M. and in L.S.M. (fig 1). In S.M., after a small initial fall, the number of living bacteria increased slowly to a peak, at 10 hours, of just over three times the initial number. Thereafter the number fell slowly and somewhat irregularly. At 48 hours the number was identical with the initial number, at 60 hours slightly lower, and at 100 hours zero. The corresponding counts obtained with L.S.M. are completely different. The number rose steeply to a peak of ten times the initial number at 8 hours, fell equally steeply to below the initial number at 16 hours, and then fell more slowly, reaching zero in 24 hours.

The curve given by 4 mg sulphathiazole per 100 ml in S.M. differed markedly from that obtained with the higher concentration in the same medium. Three peaks, each followed by a fall, occurred within the first 36 hours. The primary peak was the highest (twenty two times the initial number), the secondary and tertiary peaks being identical at fourteen times the initial number. Following the third peak there was a very slow fall to slightly below the initial number at 100 hours and to zero at 312 hours. The curve given by the same concentration of sulphathiazole in L.S.M. presents a complete contrast. The two curves are almost identical up to 6 hours, but in L.S.M. the peak (twelve times the initial number) was reached at that time and the count then fell sharply to below the initial count at 16 hours and to zero at 24 hours.

equally rapid fall to zero within a period which was sometimes as short as 24 hours and rarely as long as 36 hours. A constituent of lemco, which we have provisionally named the L substance, potentiates sulphathiazole so that it acts as a bactericidal rather than as a bacteriostatic substance.

The presence of L substance in extracts of meat and in serum, red cells and urine suggests that it is generally present in the tissues and fluids of the body. The demonstration that, in a synthetic medium free from sulphonamide antagonising substances and in serum and urine, the combination of sulphonamide and L substance behaves bactericidally strongly suggests that sulphonamides *in vivo* have more than the bacteriostatic or bacteriostatic effect generally attributed to them. It is therefore claimed that, to explain the therapeutic effects of the sulphonamides, it is unnecessary to evoke the "ordinary defence mechanisms" of the body. Sulphonamides, potentiated by a naturally occurring constituent of the body, can kill invading bacteria sensitive to their action, provided that these are not present in inaccessible situations, in excessive numbers, or in association with such powerfully antagonistic substances as pus.

The possible identity of L substance and the potentiator of sulphonamide action which Walker et al. (1947) investigated and to which they attribute the Harper and Cawston effect has been considered. For convenience we shall refer to this as the E (erythrocyte) substance. The two substances differ in five respects.

- 1 L substance potentiates sulphonamides so that in nutrient media free from antagonistic substances their action on bacteria sensitive to them is bactericidal rather than bacteriostatic. E substance neutralises the sulphonamide antagonising substances present in peptone. This action is termed neutralisation merely for convenience without implying any theory about how the E substance acts.
- 2 The L effect can be demonstrated immediately after the addition of material containing the L substance to the culture medium. For demonstration of the Harper and Cawston effect material containing the E substance must have been incorporated in the medium for at least some hours before it is tested.
- 3 L substance is present in meat extracts, serum, red blood-cells, urine, and yeast. E substance has been described as occurring exclusively in red blood-cells, particularly those of the horse. It is only right to point out, however, that it may have a wider distribution than has been realised. The experiment recorded in table IV shows that it (or a substance with similar action) is present in lemco. The actions of both L and E substances in a particular material may be masked, as in the case of L substance in lemco by the simultaneous presence of sulphonamide-antagoniser. The presence of the substances can then be demonstrated only if they are present in greater concentration than the antagoniser and only by the use of the material in suitable dilution.
- 4 The red blood-cells of man and horse contain both L and E substances but the proportions in which they occur in the two types of cell differ.
- 5 L substance is thermostable. E substance (according to Walker et al.) is thermolabile.

For these reasons we have no hesitation in affirming our belief that the sulphonamide potentiator, which we term L substance, is different from the substance which counteracts the sulphonamide antagonising action of peptone, and which is believed to be the active agent in the production of the Harper and Cawston effect.

The production of L substance by yeast suggests the possibility that it, and also E substance, can be produced by some species of bacteria. If this is found to happen there would be little difficulty in explaining the varied sensitivities of different bacterial species to sulphonamides in culture media containing sulphonamide antagonising substances.

It must be emphasised that throughout this research a single strain of one bacterial species has been used. It would be rash to assume that what is true of it is necessarily true of other species, but it must be regarded as highly improbable that the phenomenon which we have considered does not also occur with other species of bacteria.

SUMMARY

- 1 The sensitivity of a bacterium to sulphonamides is grossly underrated when ordinary culture media are used.
- 2 Treatment of such media by the method of Harper and Cawston increases the apparent sensitivity of the bacterium to sulphonamides, but only to a limited extent.
- 3 *Bacterium coli*, which grows well in a simple synthetic medium, is much more sensitive to sulphonamides in a synthetic medium than it is in media treated by the method of Harper and Cawston.
- 4 An improved synthetic medium is described.
- 5 The action of sulphathiazole on *Bact. coli* in synthetic medium is bacteriostatic rather than bactericidal or bactericidal.
- 6 The addition of a small amount (1/20,000) of lemco to synthetic medium potentiates sulphathiazole so that its action is bactericidal.
- 7 The substance responsible for the potentiating action of lemco is present in meat extracts, serum, red blood-cells, urine, and yeast.
- 8 The provisional name, L substance, has been given to this constituent of lemco.
- 9 The L substance, which is basic, has been concentrated and partially purified but not yet identified.
- 10 Since L substance is present in various body fluids which contain little, if any, sulphonamide antagonisers, it is suggested that, in the living body, the action of sulphonamides is bactericidal rather than bacteriostatic or bacteriostatic, and that, to explain their therapeutic effect, it is unnecessary to evoke the "ordinary defence mechanisms" of the body.
- 11 The L substance is different from the substance in horse red blood-cells which is responsible for the Harper and Cawston effect.

It gives us great pleasure to acknowledge our indebtedness to the Medical Research Council of Ireland grants from which have rendered it possible for one of us (G. C. W.) and Mr Boggust to engage in the work described here. We are most grateful to Professor Fearon and Mr Boggust, to our colleagues and the staff of the department of bacteriology, and to many others for the advice and assistance which they have so willingly given us.

horse red blood cells, which Walker et al (1947) consider the main, if not the sole, factor responsible for the Harper and Cavston effect. There is general agreement that this effect is better demonstrated by horse hæmolyse than by any other material, and that, for the most complete demonstration of the effect, the material must be left for some time in contact with the culture medium before the medium is heated or used. According to Walker et al, the potentiator, as present in the hæmolyse, is thermolabile, but, after it has been in contact with the medium, the medium does not regain its sulphonamide antagonising properties on being boiled.

Human and horse red blood cells were washed in saline solution and hæmolyzed with distilled water. The hæmolyse so obtained were added in various proportions (expressed in terms of packed cell volumes) to S M, with and without peptone, and at the same time the necessary controls were set up. All these fluids were kept at room temperature for 18 hours. They were next heated to 100°C, and kept at that temperature for 15 minutes. The coagula were removed by centrifuging from the fluids to which hæmolyse had been added, and all the fluids were again heated at 100°C for 15 minutes. When they were cold, the necessary amount of sulphathiazole solution in S M was added to give a concentration of 16 mg per 100 ml. The fluids, in duplicate 5 ml amounts, were inoculated, incubated, and tested in the usual way. The technique was designed to elicit the greatest Harper and Cavston effect, and to determine, under comparable conditions, the L effect of the contents of horse and human red blood cells. The figures in table IX are the means of the colony counts given by the duplicate bottles.

The upper half of the table shows the results of the tests of the two hæmolyse for L effect. Human hæmolyse obviously contained much more L substance than did that of the horse. If more closely spaced dilutions had been tested, the end points would probably have been about 1/200 for horse and 1/1200 for human hæmolyse, the titres being expressed in terms of packed cell volume.

The lower half of the table shows the results of tests of the hæmolyse for Harper and Cavston effect. The presence of 1/5000 peptone antagonised the bacteriostatic action of sulphathiazole (16 mg per 100 ml) in synthetic medium to such an extent as to give an uncountable number of colonies (many thousands) per loop after 36 hours' incubation, and, when incubation was prolonged for a further 24 hours, turbidity. The presence of horse hæmolyse in dilutions up to 1/1600 completely neutralised the sulphonamide antagonising action of peptone, and this neutralisation was so complete that the L substance also present in horse hæmolyse, was able to exercise its effect in the same dilution as it did in synthetic medium to which no peptone had been added. Human hæmolyse also showed some ability to neutralise

the sulphonamide antagonising action of peptone, but only to a dilution of 1/400. Further, it seems that with human hæmolyse, even in high concentrations, the neutralisation was less complete than with horse hæmolyse. Despite its high content of L substance, human hæmolyse did not produce zero counts even when it was present in a concentration as high as 1/25.

This experiment shows that horse and human hæmolyse contain both L substance and the substance responsible for the Harper and Cavston effect, but that the proportion of the two substances is different in the two hæmolyse.

Mr W A Boggust, working under the direction of Prof W Fearon, has attempted to isolate and identify the L substance. Concentrates very rich in it have been prepared from autolysed baker's yeast after deproteinisation and ethanol fractionation followed by selective adsorption. The L substance is basic but has not so far been identified with any of the following basic compounds known to be present in yeast: simple alkyl amines, arginine, lysine, histidine, betaines, guanidines, purines, pyrimidines, aneurine (thiamine), or tryptamine. Work on the chemical nature of the L substance is being actively pursued.

DISCUSSION

Two quotations will suffice to show the currently accepted view on the action of sulphonamides on bacteria in the body.

"Sulfonamides are primarily, if not entirely, bacteriostatic in vitro, presumably relying on host defense mechanisms for final elimination of the bacteria in vivo" (Dubos 1948).

"The concentrations of sulphonamides in the blood (5-15 mg per 100 ml) which are obtained by therapeutic doses do not kill organisms but inhibit their growth so that they are dealt with by the ordinary defence mechanisms" (Dunlop 1950).

The study of the action of sulphonamides on bacteria in vitro has been rendered difficult by the presence in culture media, as usually prepared, of sulphonamide antagonising substances. We have avoided this difficulty by using (1) synthetic media relatively or completely free from these substances, and (2) a bacterium which grows well in such simple media.

Most of those who have studied the antibacterial action of the sulphonamides have accepted, as their criteria of activity, the absence of turbidity in fluid media or of colony formation on solid media and for this reason have not been able to distinguish the killing of bacteria from inhibition of their growth. The technique used by us enabled us to follow the action of sulphonamides on bacteria in the region where their numbers were too small to produce turbidity in fluid media, and it was owing to this that the phenomenon with which we are concerned was discovered.

In the synthetic medium which we used the antibacterial action of very low concentrations of sulphathiazole on *Bact coli* was demonstrated. The action has been described as bacteriostatic rather than bacteriostatic, since the sulphonamide though it restrains the multiplication of the bacteria does not entirely prevent it, as would a truly bacteriostatic substance. Although, in the presence of sulphathiazole, the number of living bacteria, after a preliminary rise, ultimately falls to zero the rate of fall is so slow as to render the application of the term bactericidal quite inappropriate.

During the course of the work we discovered that the addition of a very small amount of lemco to synthetic medium containing sulphathiazole completely altered the effect of the sulphonamide on the organism. After a rapid increase, over a period of a few hours, in the number of living bacteria present, there was an almost

equally rapid fall to zero within a period which was sometimes as short as 24 hours and rarely as long as 36 hours. A constituent of lemco, which we have provisionally named the L substance, potentiates sulphathiazole so that it acts as a bactericidal rather than as a bacteriostatic substance.

The presence of L substance in extracts of meat and in serum, red cells, and urine suggests that it is generally present in the tissues and fluids of the body. The demonstration that in a synthetic medium free from sulphonamide antagonising substances and in serum and urine, the combination of sulphonamide and L substance behaves bactericidally strongly suggests that sulphonamides *in vivo* have more than the bacteriostatic or bacteriostatic effect generally attributed to them. It is therefore claimed that, to explain the therapeutic effects of the sulphonamides, it is unnecessary to evoke the "ordinary defence mechanisms" of the body. Sulphonamides, potentiated by a naturally occurring constituent of the body, can kill invading bacteria sensitive to their action, provided that these are not present in inaccessible situations, in excessive numbers, or in association with such powerfully antagonistic substances as pus.

The possible identity of L substance and the potentiator of sulphonamide action which Walker et al. (1947) investigated and to which they attribute the Harper and Cawston effect has been considered. For convenience we shall refer to this as the E (erythrocyte) substance. The two substances differ in five respects:

- 1 L substance potentiates sulphonamides so that in nutrient media free from antagonistic substances their action on bacteria sensitive to them is bactericidal rather than bacteriostatic. E substance neutralises the sulphonamide antagonising substances present in peptone. This action is termed neutralisation merely for convenience without implying any theory about how the E substance acts.
- 2 The L effect can be demonstrated immediately after the addition of material containing the L substance to the culture medium. For demonstration of the Harper and Cawston effect material containing the E substance must have been incorporated in the medium for at least some hours before it is tested.
- 3 L substance is present in meat extracts, serum, red blood-cells, urine, and yeast. E substance has been described as occurring exclusively in red blood-cells, particularly those of the horse. It is only right to point out, however, that it may have a wider distribution than has been realised. The experiment recorded in table IV shows that it (or a substance with similar action) is present in lemco. The actions of both L and E substances in a particular material may be masked, as in the case of L substance in lemco by the simultaneous presence of sulphonamide antagonist. The presence of the substances can then be demonstrated only if they are present in greater concentration than the antagonist and only by the use of the material in suitable dilution.
- 4 The red blood-cells of man and horse contain both L and E substances but the proportions in which they occur in the two types of cell differ.
- 5 L substance is thermostable, E substance (according to Walker et al.) thermolabile.

For these reasons we have no hesitation in affirming our belief that the sulphonamide potentiator, which we term L substance, is different from the substance which counteracts the sulphonamide antagonising action of peptone, and which is believed to be the active agent in the production of the Harper and Cawston effect.

The production of L substance by yeast suggests the possibility that it, and also E substance, can be produced by some species of bacteria. If this is found to happen, there would be little difficulty in explaining the varied sensitivities of different bacterial species to sulphonamides in culture media containing sulphonamide antagonising substances.

It must be emphasised that throughout this research a single strain of one bacterial species has been used. It would be rash to assume that what is true of it is necessarily true of other species, but it must be regarded as highly improbable that the phenomenon which we have considered does not also occur with other species of bacteria.

SUMMARY

- 1 The sensitivity of a bacterium to sulphonamides is grossly underrated when ordinary culture media are used.
- 2 Treatment of such media by the method of Harper and Cawston increases the apparent sensitivity of the bacterium to sulphonamides, but only to a limited extent.
- 3 *Bacterium coli*, which grows well in a simple synthetic medium, is much more sensitive to sulphonamides in a synthetic medium than it is in media treated by the method of Harper and Cawston.
- 4 An improved synthetic medium is described.
- 5 The action of sulphathiazole on *Bact. coli* in synthetic medium is bacteriostatic rather than bactericidal or bactericidal.
- 6 The addition of a small amount (1/20,000) of lemco to synthetic medium potentiates sulphathiazole so that its action is bactericidal.
- 7 The substance responsible for the potentiating action of lemco is present in meat extracts, serum, red blood-cells, urine and yeast.
- 8 The provisional name, L substance, has been given to this constituent of lemco.
- 9 The L substance, which is basic, has been concentrated and partially purified but not yet identified.
- 10 Since L substance is present in various body fluids which contain little, if any, sulphonamide antagonisers, it is suggested that, in the living body, the action of sulphonamides is bactericidal rather than bacteriostatic or bacteriostatic, and that, to explain their therapeutic effect, it is unnecessary to evoke the "ordinary defence mechanisms" of the body.
- 11 The L substance is different from the substance in horse red blood-cells which is responsible for the Harper and Cawston effect.

THE FEEDING OF SCHOOL-CHILDREN

FRANKCON ROBERTS

M.A., M.D. Camb., F.F.R.

From Addenbrooke's Hospital, Cambridge

IN a secondary modern school in Cambridgeshire, two problems have arisen in connection with the feeding of the children. The first is that despite every inducement not more than 27% of the children can be made to drink milk—a figure much lower than in neighbouring schools and lower than the average for the whole country. The second concerns the quantity of food which should be provided in the school dinner. Estimates made during the war on five successive days by an official of the Ministry of Education gave calorie equivalents ranging between 580 and 780, with an average of 649 from sample helpings and 705 from the total quantity of ingredients. As the result of this report the quantity was increased and was found a year later to give a value of 845 from total ingredients. Even this figure, however, failed to satisfy the official who pointed out that the Ministry's recommendation was 1000 calories.

The unpopularity of milk, together with the fact that the dinner, to judge by the amount left uneaten, appeared to be more than sufficient though well below the Ministry's standard, naturally caused the governors and staff no little concern. Should the children be yet further cajoled into drinking milk, and in view of the waste at 800 calories, should the dinner really be stepped up to 1000? In an attempt to find the answer to these questions I resolved to study radiologically the state of the children's stomachs at intervals throughout the day under varying conditions of intake.

THE DAILY INTAKE

The children are drawn from a large central village (partly industrialised) and from the surrounding rural district, travelling to and from the latter by bus or bicycle. With few exceptions the children are well cared for. Wages are good and employment is full. Many of the parents grow their own vegetables and keep hens. Medical inspection has consistently revealed a high standard of health with no trace of any deficiency diseases. Many of the children begin the day in luxury (compared with my own childhood) by having tea brought to them in bed by their mothers. Breakfast usually consists either of cereals followed by bread and butter or of bread and butter with an egg or bacon. On arriving home at 4.30 p.m. they have either a plain tea, followed at 9 by a substantial meal which includes cheese, meat, or something fried, or a high tea with perhaps pork-pie, bread and butter, and salad, followed at 9 by tea or cocoa with bread and butter or cake. Further, about half the children take to school a packed lunch which they eat during the break.

Assembly is at 9.15 a.m. Before this investigation was conducted, milk with or without the packed lunch was taken, as it was and still is, I believe, at other schools, during the morning break, between 10.35 and 10.45. The packed lunch has to be seen to be believed. It consists of buns, cakes, chocolate, or cheese or potted-meat sandwiches in substantial amount, often having a calorie value of 250. Since $\frac{1}{2}$ pint of milk contains 126 calories, if a child took this plus 240 calories in sandwiches and followed it up at 12.30 with the dinner of 1000 calories which the Ministry wants him to take, he would be stoking himself up with 1366 calories within two hours—an impossibility, as I shall show.

I have on many occasions partaken of the dinner and have invariably found it well cooked, adequate, and appetising. I have observed, however, that with a meal of about 800 calories a considerable amount, taken collectively, remains uneaten. Green vegetables are less

popular than one would expect in a district where they are grown in such abundance. Many children, particularly the girls, take no meat. They exhibit, too, the most curious likes and dislikes. Baked pudding is unpopular, steamed pudding on the other hand is popular but is preferred unflavoured to flavoured.

The reasons for the aversion to milk are several. During the war delivery was unreliable and it was not always possible to avoid mixing fresh milk with stale. Some children dislike it cold but most of them dislike it whether warm or cold. Many parents do not insist on their drinking milk at home. The mania for slimming, caught no doubt from elder sisters, infects girls at quite an early age and is partly responsible. Poverty was of course no reason, since milk could always be obtained free of charge in deserving cases. Before milk became free for all, 90 bottles were taken by 220 children, after it was free the number dropped to 60. This diminution was, however, mainly due to the fact that when children paid for it a few took two, three, or even four bottles, while after it was free no child was allowed more than one. There seems to be no reason why supplementary milk should not be allowed on payment.

In my opinion, which is supported by many experienced people whose judgment I respect, the chief reason for the refusal of milk is that children, at any rate those in this locality, are given in one form or another more food than they really need. One boy, who lived on a farm, scorned the school dinner because no partridges or pheasants were provided. Estimates made from information provided by the children (admittedly an unreliable method but the only one available) gave an average daily intake, including milk and a fully eaten dinner, of at least 3000 calories. Altogether, therefore, so far as quantity is concerned, the children are well fed.

METHODS OF INVESTIGATION

A small quantity of barium sulphate given on a completely empty stomach is sufficient to fill the lumen except for that part at the fundus occupied by air. Any contents already present, even as little as 25 ml., can be readily seen because the barium, by reason of its weight, passes through them without mixing with them, coming to rest at the lower pole. If the quantity of residual food is large the barium occupies the lower pole and extends a little way along the greater curvature, while the upper limit of the contents forms a wide fluid level below the air at the fundus. The upper and lower limits are thus clearly shown, and the greater and lesser curvatures (the latter not always distinctly) can be identified by the faint difference in density between the stomach and the adjacent viscera. Distortion being minimised by adopting a 6 ft. distance, the films show with sufficient accuracy the volume of the contents.

This method was used to determine the state of the stomach at the onset of the experiments. In order to study the effect of food given subsequently it was supplemented by a second. Here the food given was mixed with a quantity of barium insufficient to affect the taste but sufficient to cast a shadow.

In the accompanying diagrams barium is indicated in solid black, and other gastric contents by horizontal lines. Absence of such lines therefore indicates that the stomach was empty before the barium was introduced. Sometimes, as in no. 3 (fig. 1) the barium is held up along the lesser curvature or in the folds of the mucosa.

Two methods were open either to study the effect of varying conditions of diet on the same children or to study each child according to his normal habits. The latter seemed preferable and was adopted except in two cases where, owing to a misunderstanding, the children were put in the wrong category.

The number of examinations made was 27. It may be objected that this number was too small to form the basis of the deductions drawn. Certainly no two stomachs are exactly alike, and no one stomach has to submit to the same experience every day. It will be appreciated, too, that these experiments take a great deal of time (as much as I could spare from my normal work) and need the co-operation of a number of people. As will be seen, however, the results are remarkably consistent. An apparently more valid objection is that the normal behaviour of the stomach was disturbed by fear. This objection, however, is quite groundless. On their visits to the hospital the children were allowed to play about in the screening room and shown each others' hearts beating, an experience which naturally aroused great interest and took their minds off themselves. The absence of fear is shown by the fact that the children subsequently importuned their teachers to be allowed to come again.

THE STOMACH AT MILK-TIME (10.35 A.M.)

Twelve children were examined at about 10.35 in order to determine what had happened to their breakfasts. The results are shown in the first column of diagrams in figs 1, 2, and 3. The stomachs showed all degrees from repletion to complete emptiness. Two surprising results emerged. In the first place, the amount of the residue was not determined by the amount of breakfast which had been eaten. Of the four with completely empty stomachs, no. 8 had had an egg and fried potatoes, no. 9 fried egg and bacon with bread and butter, no. 10 bacon and chip potatoes with bread and butter, and no. 4 sausages and tomatoes with bread and butter. Of those with the largest residues, no. 1 had had bread and marmalade, no. 2 'Farmer's Glory,' no. 3 'Shredded Wheat' and two 'Spam' sandwiches, and no. 5 bacon and one piece of bread and butter. The amount of the residue therefore appeared to reflect individual differences in the rate of digestion.

Equally surprising was the relation between the state of the stomach and the desire for milk. Of five habitual non-milk takers, the stomach was completely empty in three, almost empty in one, and contained a fair residue

in one. Of the four who habitually took milk, the stomach was completely empty in one, while in the other three there was a considerable residue. Of the three who habitually took packed lunch as well as milk, one had a moderate and the others a large residue. The desire for mid-morning nourishment is therefore not determined by the emptiness of the stomach. Apart from parental encouragement it seems that some children feel the need to keep their stomachs full while others do not.

THE STOMACH AT DINNER TIME (12.30 P.M.)

Immediately after the above examinations the children were divided into three groups. Group A (nos. 1-4, fig. 1) were given $\frac{1}{2}$ pint of milk. Of those in this group all habitually took milk without lunch, except one who took it only in winter (the examination was made in summer). Group B (nos. 5-7, fig. 2) were given $\frac{1}{2}$ pint of milk together with the lunch which they had brought (their usual habit). Group C (nos. 8-12, fig. 3) were given nothing. Of these, the first three normally took nothing, no. 11 took milk, and no. 12 took milk and lunch. The last two appeared in this group by accident.

The results are shown in the second column of diagrams in figs. 1-3. In those who had taken nothing the stomach was completely empty. Of the seven who had taken milk with or without lunch there was a moderate residue in two and a large residue in five. The state of the stomach was reflected in appetite. All with empty stomachs and the two with moderate residues felt hungry, while of the five with large residues only one felt hungry.

THE EFFECT OF LUNCH WITHOUT MILK

Four other boys took at 10.35 A.M. the lunch they had brought with them. This consisted of potted meat sandwiches weighing roughly 80 to 90 g. At dinner time some of this was still present in the stomach but, except in one boy, the amount was very much less than the amount after milk without lunch.

Fig. 1—Milk taken at 10.45 A.M.

Fig. 2—Milk and lunch taken at 10.45 A.M.

Fig. 3—No milk or lunch taken

GASTRIC CAPACITY AND DIGESTION-RATE

The next problem was to discover the quantity of food which could be eaten at dinner and the time taken to digest it. The experiment was carried out on three boys, of whom one (no. 13) habitually took no milk or lunch, one (no. 14) took milk only, and one (no. 15) took both milk and lunch. After they had been examined at 10.35 A.M., no. 14 was given milk, no. 15 milk and lunch, and no. 13 nothing. Examination at 12.30 P.M. (fig. 4) confirmed the results described above. In no. 13 the stomach was empty, in no. 14 there was a moderate residue, and in no. 15 a large residue.

At 12.30 P.M. the boys were given dinner at the hospital. A meal of 800 calories was aimed at, actually it worked out at 788. It consisted of stewed steak with peas and potatoes followed by baked gingerbread pudding with custard sauce. Into the potatoes and sauce a small

Many of the children begin the day in luxury (compared with my own childhood) by having tea brought to them in bed by their mothers. Breakfast usually consists either of cereals followed by bread and butter or of bread and butter with an egg or bacon. On arriving home at 4.30 P.M. they have either a plain tea, followed at 9 by a substantial meal which includes cheese, meat, or something fried, or a high tea with perhaps pork-pie, bread and butter, and salad, followed at 9 by tea or cocoa with bread and butter or cake. Further, about half the children take to school a packed lunch which they eat during the break.

Assembly is at 9.15 A.M. Before this investigation was conducted, milk with or without the packed lunch was taken, as it was and still is, I believe, at other schools, during the morning break, between 10.35 and 10.45. The packed lunch has to be seen to be believed. It consists of buns, cakes, chocolate, or cheese or potted-meat sandwiches in substantial amount, often having a calorie value of 250. Since $\frac{1}{2}$ pint of milk contains 126 calories, if a child took this plus 240 calories in sandwiches and followed it up at 12.30 with the dinner of 1000 calories which the Ministry wants him to take, he would be stoking himself up with 1366 calories within two hours—an impossibility, as I shall show.

I have on many occasions partaken of the dinner and have invariably found it well cooked, adequate, and appetising. I have observed, however, that with a meal of about 800 calories a considerable amount, taken collectively, remains uneaten. Green vegetables are less

popular than one would expect in a district where they are grown in such abundance. Many children, particularly the girls, take no meat. They exhibit, too, the most curious likes and dislikes. Baked pudding is unpopular, steamed pudding on the other hand is popular but is preferred unflavoured to flavoured.

The reasons for the aversion to milk are several. During the war delivery was unreliable and it was not always possible to avoid mixing fresh milk with stale. Some children dislike it cold but most of them dislike it whether warm or cold. Many parents do not insist on their drinking milk at home. The mania for slimming, caught no doubt from elder sisters, infects girls at quite an early age and is partly responsible. Poverty was of course no reason, since milk could always be obtained free of charge in deserving cases. Before milk became free for all, 90 bottles were taken by 220 children, after it was free the number dropped to 60. This diminution was, however, mainly due to the fact that when children paid for it a few took two, three, or even four bottles, while after it was free no child was allowed more than one. There seems to be no reason why supplementary milk should not be allowed on payment.

In my opinion, which is supported by many experienced people whose judgment I respect, the chief reason for the refusal of milk is that children, at any rate those in this locality, are given in one form or another more food than they really need. One boy, who lived on a farm, scorned the school dinner because no partridges or pheasants were provided. Estimates made from information provided by the children (admittedly an unreliable method but the only one available) gave an average daily intake, including milk and a fully eaten dinner, of at least 3000 calories. Altogether, therefore, so far as quantity is concerned, the children are well fed.

METHODS OF INVESTIGATION

A small quantity of barium sulphate given on a completely empty stomach is sufficient to fill the lumen except for that part at the fundus occupied by air. Any contents already present, even as little as 25 ml., can be readily seen because the barium, by reason of its weight, passes through them without mixing with them, coming to rest at the lower pole. If the quantity of residual food is large the barium occupies the lower pole and extends a little way along the greater curvature, while the upper limit of the contents forms a wide fluid level below the air at the fundus. The upper and lower limits are thus clearly shown, and the greater and lesser curvatures (the latter not always distinctly) can be identified by the faint difference in density between the stomach and the adjacent viscera. Distortion being minimised by adopting a 6 ft. distance, the films show with sufficient accuracy the volume of the contents.

This method was used to determine the state of the stomach at the onset of the experiments. In order to study the effect of food given subsequently it was supplemented by a second. Here the food given was mixed with a quantity of barium insufficient to affect the taste but sufficient to cast a shadow.

In the accompanying diagrams barium is indicated in solid black, and other gastric contents by horizontal lines. Absence of such lines therefore indicates that the stomach was empty before the barium was introduced. Sometimes, as in no. 3 (fig. 1), the barium is held up along the lesser curvature or in the folds of the mucosa.

Two methods were open either to study the effect of varying conditions of diet on the same children, or to study each child according to his normal habits. The latter seemed preferable and was adopted except in two cases where, owing to a misunderstanding, the children were put in the wrong category.

The number of examinations made was 27. It may be objected that this number was too small to form the basis of the deductions drawn. Certainly no two stomachs are exactly alike, and no one stomach has to submit to the same experience every day. It will be appreciated, too, that these experiments take a great deal of time (as much as I could spare from my normal work) and need the co-operation of a number of people. As will be seen, however, the results are remarkably consistent. An apparently more valid objection is that the normal behaviour of the stomach was disturbed by fear. This objection, however, is quite groundless. On their visits to the hospital the children were allowed to play about in the screening room and shown each others' hearts beating, an experience which naturally aroused great interest and took their minds off themselves. The absence of fear is shown by the fact that the children subsequently importuned their teachers to be allowed to come again.

THE STOMACH AT MILK TIME (10 35 A.M.)

Twelve children were examined at about 10 35 in order to determine what had happened to their breakfasts. The results are shown in the first column of diagrams in figs 1, 2, and 3. The stomachs showed all degrees from repletion to complete emptiness. Two surprising results emerged. In the first place the amount of the residue was not determined by the amount of breakfast which had been eaten. Of the four with completely empty stomachs, no 8 had had an egg and fried potatoes, no 9 fried egg and bacon with bread and butter, no 10 bacon and chip potatoes with bread and butter, and no 4 sausages and tomatoes with bread and butter. Of those with the largest residues, no 1 had had bread and marmalade, no 2 'Farmer's Glory,' no 3 'Shredded Wheat' and two 'Spam' sandwiches, and no 8 bacon and one piece of bread and butter. The amount of the residue therefore appeared to reflect individual differences in the rate of digestion.

Equally surprising was the relation between the state of the stomach and the desire for milk. Of five habitual non milk takers, the stomach was completely empty in three, almost empty in one, and contained a fair residue

in one. Of the four who habitually took milk, the stomach was completely empty in one, while in the other three there was a considerable residue. Of the three who habitually took packed lunch as well as milk, one had a moderate and the others a large residue. The desire for mid morning nourishment is therefore not determined by the emptiness of the stomach. Apart from parental encouragement it seems that some children feel the need to keep their stomachs full while others do not.

THE STOMACH AT DINNER TIME (12 30 P.M.)

Immediately after the above examinations the children were divided into three groups. Group A (nos 1-4, fig 1) were given $\frac{1}{2}$ pint of milk. Of those in this group all habitually took milk without lunch, except one who took it only in winter (the examination was made in summer). Group B (nos 5-7, fig 2) were given $\frac{1}{2}$ pint of milk together with the lunch which they had brought (their usual habit). Group C (nos 8-12, fig 3) were given nothing. Of these, the first three normally took nothing, no 11 took milk, and no 12 took milk and lunch. The last two appeared in this group by accident.

The results are shown in the second column of diagrams in figs 1-3. In those who had taken nothing the stomach was completely empty. Of the seven who had taken milk with or without lunch there was a moderate residue in two and a large residue in five. The state of the stomach was reflected in appetite. All with empty stomachs and the two with moderate residues felt hungry, while of the five with large residues only one felt hungry.

THE EFFECT OF LUNCH WITHOUT MILK

Four other boys took at 10 35 A.M. the lunch they had brought with them. This consisted of potted meat sandwiches weighing roughly 80 to 90 g. At dinner time some of this was still present in the stomach, but, except in one boy, the amount was very much less than the amount after milk without lunch.

Fig 1—Milk taken at 10 40 A.M.

Fig 2—Milk and lunch taken at 10 40 A.M.

Fig 3—No milk or lunch taken

GASTRIC CAPACITY AND DIGESTION RATE

The next problem was to discover the quantity of food which could be eaten at dinner and the time taken to digest it. The experiment was carried out on three boys, of whom one (no 13) habitually took no milk or lunch, one (no 14) took milk only, and one (no 15) took both milk and lunch. After they had been examined at 10 35 A.M., no 14 was given milk, no 15 milk and lunch, and no 13 nothing. Examination at 12 30 P.M. (fig 4) confirmed the results described above. In no 13 the stomach was empty, in no 14 there was a moderate residue, and in no 15 a large residue.

At 12 30 P.M. the boys were given dinner at the hospital. A meal of 800 calories was aimed at, actually it worked out at 788. It consisted of stewed steak with peas and potatoes followed by baked gingerbread pudding with custard sauce. Into the potatoes and sauce a small

Fig. 4—For explanation see text

quantity of barium was incorporated. The boys detected no difference in the taste but they did wonder why the potatoes looked so white. They attacked the meal with zest but none of them succeeded in finishing it. They had had enough at about 700 calories.

They were examined immediately after dinner, and again at 4:30 P.M., with the results shown in the fourth and fifth column of drawings in fig. 4. The meal had caused the stomach to be distended to a maximum (fig. 7). At 4:30 P.M. a large residue was still present in two boys, a moderate one in the third. To this residue gastric juice largely contributed, as was obvious from the diminution in the opacity of the gastric contents.

Fig. 5—For explanation see text.

THE EFFECT OF GIVING MILK EARLIER

To satisfy the principle, which will be discussed later, that the stomach should be empty by dinner time, three courses of action suggested themselves. The dinner could be deferred to 1:0 P.M., milk could be given with dinner, or milk could be given earlier in the morning. The first of these proved impracticable owing to a Ministry regulation that two hours' instruction must be completed by 4 P.M. This would not allow sufficient time to clear up before lessons began. The second course seemed hardly worth exploring. If so many children could not take the meal provided without milk, still less could they take it with milk. Moreover those parents who encouraged their children to take milk would react by increasing the quantity of the packed lunch. There remained therefore the third course, to give the milk earlier.

Four boys were given milk at 9:40 A.M. It will be seen (fig. 5) that in all of them the stomach was completely or nearly empty at dinner time. (Compare the third column of diagrams in figs. 4 and 5.) The required condition of an empty stomach at dinner time is therefore obtained by this simple procedure, which, as the result of these experiments, has been permanently adopted at this school, the milk being given directly after assembly and prayers. The new system has, however, not made milk more popular. Such an effect was indeed not to be expected, but the teachers have formed the impression that appetites at dinner have thereby been improved.

At 12:30 P.M. these boys were given a meal of 800 calories. All failed to finish it except one, a big boy. The results (fig. 5, columns 4 and 5) show that here again a considerable residue was still present at 4:30.

THE QUANTITY AND DIGESTION-RATE OF THE SCHOOL DINNER

It remained to compare the effect of the school dinner with the effect of the measured dinner. Three boys were examined directly after a school dinner and again at 4:30 P.M. (fig. 6). For two reasons conclusions from this experiment can be drawn only with reserve. First, the number of examinations was too small. Secondly, the experiment had perforce to be carried out on boys other than those who took the measured dinner. It will be seen, however, that the degree of gastric distension is much less than after the measured dinner. So far as it goes the evidence confirms the impression I have formed from many visits that the school dinner actually consumed is substantially less than the dinner of 800 calories which was provided at the hospital. Yet it is amply satisfying.

THE EMPTYING RATE OF THE STOMACH

It will be noted that even with a meal of less than 800 calories there is still a substantial residue four hours after it is taken. This means that prevalent ideas must be discarded. As the result of routine radiological examinations it has come to be

Fig. 6—Stomachs after a school dinner

Fig 7.—Stomach directly after a meal of about 700 calories note great distension

believed that the stomach is normally empty in from three to four hours. This, however, is true only for a suspension of barium sulphate which makes no digestive demands on the stomach, evokes little gastric secretion, and is treated as a foreign body of abnormal weight. We are apt to forget that the stomach is a living thing. A barium meal is in fact no meal at all. In the social group under consideration the stomach is about one third full four hours after dinner and is filled up again at tea and again at supper. In children who take mid morning food the stomach, apart from an hour or so before 10.30 A.M., is more full than empty for the greater part of the waking hours.

By the method here adopted it is possible to arrive at a rough estimate of the maximum capacity of the stomach. On the assumption that the width of the stomach in the sagittal plane is equal to the width in the coronal plane, simple calculation shows that, in no 18 for instance, the contents attain a volume of over one litre (about two pints). To the dinner itself is added the water drunk, the residue from lunch, and also the gastric juice which at first may well contribute more than is lost through the pylorus. Four hours later the contents measure at least a third of the maximum amount.

THE EFFECT OF MILK ON BODY WEIGHT

An attempt was made over a period of three years to assess the effect of milk, with or without lunch, on body-weight. The result however was inconclusive. Many children took milk seasonally, and some changed their habits during the period. Moreover, despite the large number of children involved, individual differences in the rate of increase in weight within each category were very great.

DISCUSSION

Children, boys especially, always have eaten and always will eat anything at any time of the day. The late M. R. James, provost of King's College, Cambridge, wrote of his school days "I and another have frequently sent out after twelve for 24 new 1d. buns or 24 new rice cakes, which were entirely forgotten by Hall time at two." Forgotten they may have been but that they had successfully negotiated the pylorus is highly improbable.

Childish instinct, however, is one thing, its parental encouragement is quite another. A practice normal to children cannot but be stimulated by the new and almost universal habit of indulgence in "elevenses." Many mothers have a horror lest their children should feel the slightest pangs of hunger even for brief moments of the day. At one school (not in this district) they congregated

round the playground during break and feed their offspring through the railings like animals at the zoo. When milk and a good dinner are provided, lunch seems to be unnecessary.

The change in national habits from the few large meals of the past (meals with which the modern generation is unable to cope) to the frequent small meals of the present means that an alteration in function has been imposed upon the stomach. From being an almost purely digestive organ it has become, in part at least, a reservoir rarely empty during the daytime. We have no evidence that this change has any ill effects, but it is at least certain that if the stomach is permanently full or half full the digestive juice is correspondingly diluted. "Don't spoil your dinner," our mothers and grandmothers were never tired of saying. It may well be that their admonitions against preprandial nibbling had a solid physiological basis. Be that as it may, we have no explanation of the widespread incidence of peptic ulceration or of its increase in young adults.

I do not claim that the results described here are applicable to children all over the country. As I have said, these children are fortunate in their home conditions and in their opportunities for obtaining food on the side. They are much more favourably situated than those living in large industrial towns. Equally, official standards laid down centrally, though essential for some groups of children, may be quite unsuitable for others. To impose and stress such standards without regard to local conditions causes unnecessary worry and heart-searching to governors and staffs who are conscientiously trying to do their best for the children under their care.

It does more. While it is essential that children should have enough to eat, it is equally important that food should not be wasted and that children should not view and participate in such wastage with indifference. Wasting food is one of our less pleasant national characteristics, and one which horrifies other nations, especially the French. Nothing is worse than to put in front of a child a quantity of food determined by authority and to give him the idea that he can leave as much as he likes uneaten. At this school vegetables have hitherto been served on to the plates with the meat. I have recommended that the children should help themselves to vegetables. They should thus learn not to take more than they think they can eat. Second helpings will of course be available.

In this matter many parents have a great deal to learn. There is no doubt that indulgence in fads and whims, so painfully obvious to the observer of a school dinner, is largely due to faulty home discipline, to indifferent cooking, and to peripatetic munching instead of sit-down meals. Not the least valuable element in the school meal is that it teaches children that dinner is to be partaken of in an orderly manner and that its nutritional value is enhanced by its being a social function. Slowly, but I believe surely, this lesson is being reinforced by the increasing facilities for teaching the art of cookery in schools and in evening classes. We may confidently expect that the discipline thus instilled will in course of time exert a profound influence on what is after all one of the main functions of the home.

CONCLUSIONS

1. At dinner-time all children who had taken milk with or without lunch two hours previously had a considerable quantity of food in the stomach. With one exception all said they were not hungry. On the other hand all children who took no milk had empty stomachs, and all said they were hungry.

2. As a general rule the children who habitually took no milk had empty stomachs at milk time, while those who habitually took milk had not completely digested their breakfasts. The desire for milk is therefore

Fig 4—For explanation see text

quantity of barium was incorporated. The boys detected no difference in the taste but they did wonder why the potatoes looked so white. They attacked the meal with zest but none of them succeeded in finishing it. They had had enough at about 700 calories.

They were examined immediately after dinner, and again at 4 30 P.M., with the results shown in the fourth and fifth column of drawings in fig 4. The meal had caused the stomach to be distended to a maximum (fig 7). At 4 30 P.M. a large residue was still present in two boys, a moderate one in the third. To this residue gastric juice largely contributed, as was obvious from the diminution in the opacity of the gastric contents.

Many children took milk seasonally, and some changed their habits during the period. Moreover, despite the large number of children involved, individual differences in the rate of increase in weight within each category were very great.

DISCUSSION

Children, boys especially, always have eaten and always will eat anything at any time of the day. The late M. R. James provost of King's College, Cambridge, wrote of his school-days "I and another have frequently sent out after twelve for 24 new $\frac{1}{4}$ d. buns or 24 new rice cakes, which were entirely forgotten by Hall time at two." Forgotten they may have been, but that they had successfully negotiated the pylorus is highly improbable.

Childish instinct, however, is one thing, its parental encouragement is quite another. A practice normal to children cannot but be stimulated by the new and almost universal habit of indulgence in "evenings." Many mothers have a horror lest their children should feel the slightest pangs of hunger even for brief moments of the day. At one school (not in this district) they congregated

round the playground during break and feed their offspring through the railings like animals at the zoo. When milk and a good dinner are provided, lunch seems to be unnecessary.

The change in national habits from the few large meals of the past (meals with which the modern generation is unable to cope) to the frequent small meals of the present means that an alteration in function has been imposed upon the stomach. From being an almost purely digestive organ it has become, in part at least, a reservoir rarely empty during the daytime. We have no evidence that this change has any ill effects, but it is at least certain that if the stomach is permanently full or half full the digestive juice is correspondingly diluted. "Don't spoil your dinner," our mothers and grandmothers were never tired of saying. It may well be that their admonitions against preprandial nibbling had a solid physiological basis. Be that as it may, we have no explanation of the widespread incidence of peptic ulceration or of its increase in young adults.

I do not claim that the results described here are applicable to children all over the country. As I have said, these children are fortunate in their home conditions and in their opportunities for obtaining food on the side. They are much more favourably situated than those living in large industrial towns. Equally, official standards laid down centrally, though essential for some groups of children, may be quite unsuitable for others. To impose and stress such standards without regard to local conditions causes unnecessary worry and heart-searching to governors and staffs who are conscientiously trying to do their best for the children under their care.

It does more. While it is essential that children should have enough to eat, it is equally important that food should not be wasted and that children should not view and participate in such wastage with indifference. Wasting food is one of our less pleasant national characteristics, and one which horrifies other nations, especially the French. Nothing is worse than to put in front of a child a quantity of food determined by authority and to give him the idea that he can leave as much as he likes uneaten. At this school vegetables have hitherto been served on to the plates with the meat. I have recommended that the children should help themselves to vegetables. They should thus learn not to take more than they think they can eat. Second helpings will of course be available.

In this matter many parents have a great deal to learn. There is no doubt that indulgence in fads and whims, so painfully obvious to the observer of a school dinner, is largely due to faulty home discipline, to indifferent cooking, and to peripatetic munching instead of sit-down meals. Not the least valuable element in the school meal is that it teaches children that dinner is to be partaken of in an orderly manner and that its nutritional value is enhanced by its being a social function. Slowly, but I believe surely, this lesson is being reinforced by the increasing facilities for teaching the art of cookery in schools and in evening classes. We may confidently expect that the discipline thus instilled will in course of time exert a profound influence on what is after all one of the main functions of the home.

CONCLUSIONS

1 At dinner time all children who had taken milk with or without lunch two hours previously had a considerable quantity of food in the stomach. With one exception all said they were not hungry. On the other hand all children who took no milk had empty stomachs, and all said they were hungry.

2 As a general rule the children who habitually took no milk had empty stomachs at milk time, while those who habitually took milk had not completely digested their breakfasts. The desire for milk is therefore

dictated not by the emptiness of the stomach but by the habit of keeping the stomach filled

3 Lunch without milk was digested more rapidly than milk without lunch

4 Whether milk had been taken or not the children failed to consume a dinner of 788 calories. The standard of 1000 calories laid down by the Ministry of Education is therefore excessive for these children

5 Advancing the milk to 9.45 A.M.—that is, three hours before dinner—secured the attainment, desirable on physiological grounds, of an empty stomach by dinner-time

6 Whether milk had been taken or not, the stomach contained a quantity (sometimes large) of food four hours after dinner

7 When milk is offered and a good dinner is provided, packed lunch appears to be unnecessary

This investigation was carried out independently of the Ministry of Education and of the local education authority. I have no professional association with the school concerned, my interest in the problem having been aroused solely through my membership of its governing body. No charge on public funds was incurred, the small expense, chiefly in films, being met by the Wilson Berkworth Research Fund administered by Addenbrooke's Hospital. The estimation of the calorie value of the diets and the preparation of the special dinners were done by Miss M. Chivers, dietitian housekeeper, Addenbrooke's Hospital. I am very grateful to her for the interest and care which she took. My thanks are also due to the governors, to Dr R. French, medical officer of health, Cambridgeshire, and to the parents of the children for allowing me to carry out the experiments, to the warden, teachers, and housekeeper of the school for their unfailing help, to Mr R. Malstrom for the drawings, and last but not least to the children for their joyous co-operation.

ACTION OF PROGUANIL ON *P. BERGHEI* INHIBITION BY *p*-AMINO BENZOIC ACID

JUNE P. THURSTON
B.Sc. Lond.

From the National Institute for Medical Research, Mill Hill, London

THE mode of action of proguanil ('Paludrine,' 'Chloroguanide') is unlike that of most antimalarials. It is connected with the action of sulphonamides, since the two types of drug produce similar morphological changes in the malaria parasite and both give rise to resistant strains of malaria, moreover, strains of *Plasmodium gallinaceum* that are resistant to sulphonamides are also resistant to proguanil.

As is well known, the action of sulphonamides on malaria parasites (as on other susceptible organisms) is inhibited by *p*-aminobenzoic acid, recent work has shown that it is also inhibited by pteroylglutamic acid (Greenberg 1949). The action of proguanil on *P. gallinaceum*, however, is not inhibited by *p*-aminobenzoic acid (Bishop and McConnachie 1948), though it is by pteroylglutamic acid. This lack of inhibition by *p*-aminobenzoic acid was interpreted as meaning that proguanil possibly interferes with the utilisation of pteroylglutamic acid rather than its synthesis from *p*-aminobenzoic acid.

EXPERIMENTAL FINDINGS

The present experiments with *P. berghei* were based on the chemotherapeutic screening tests described by Thurston (1950). Infected mice were dosed by mouth for four days with the minimum effective dose of proguanil or sulphadiazine. *p*-Aminobenzoic acid or pteroylglutamic acid was given by mouth immediately after the dose of the drug. Thin blood films, stained

with Giemsa, were examined on the day after treatment ended, and the percentage of erythrocytes which were parasitized was recorded.

The results of the experiments (see table) show that the action of proguanil was inhibited by *p*-aminobenzoic acid, the minimum effective dose being 0.1–0.01 mg per 20 g mouse. Its action was not inhibited by pteroylglutamic acid. These results are in opposition to the findings with *P. gallinaceum* and show that with *P. berghei* the action of proguanil more closely resembles that of the sulphonamides than had previously been supposed, though fundamental differences still remain. Probably proguanil affects some reaction in which *p*-aminobenzoic acid is involved but which does not lead to the synthesis of pteroylglutamic acid.

The action of sulphadiazine was inhibited by both *p*-aminobenzoic acid and pteroylglutamic acid. This is in accord with previous reports of inhibition of its action on bacteria and in other species of malaria.

SUMMARY

The action of proguanil against *P. berghei* was found to be inhibited by *p*-aminobenzoic acid but not by pteroylglutamic acid. Against *P. gallinaceum* its action had previously been shown to be inhibited by pteroylglutamic acid but not by *p*-aminobenzoic acid. The action of sulphonamides on malaria parasites is known to be inhibited by both substances.

My thanks are due to Dr Frank Hawking for encouragement in this work and to Miss D. Ryder for technical assistance.

The factitious induction in man of a naturally occurring disorder compels the attention of every observer of disease. For this reason, and as a warning and a reminder, we recount the clinical story of a man who came under our care in the final stage of a calamity which had over taken him in 1945 and had been diagnosed as sprue.

CASE-RECORD

Mr W, single and intelligent, had spent the greater part of his 48 years at sea with the Merchant Navy, in all climates.

History of Present Illness

Until 1941 his medical record was immaculate but in that year he developed a duodenal ulcer and by 1944 he could no longer follow the sea. In the autumn of 1945 he had a severe hæmatemesis and it is recorded that at operation in December a large active duodenal ulcer was found and a posterior gastro-enterostomy was constructed. The patient said that seven days after his operation he was seized of abdominal pain, distension, and vomiting, and that this was overcome by gastric suction and saline infusion during a week of acute distress. But convalescence was slow: he was troubled by flatulence, hungry yet losing weight, he had little energy and when, eight weeks after his operation, he developed swelling of his legs and feet and a frequent offensive diarrhoea, a melancholy clouded his native optimism.

As the year 1946 went by his state worsened and became more complex. Towards July both thighs and the lower abdominal wall became sodden with œdema: the dropsy was gravitational and the emptied limbs would fill in a few minutes with a conscious flush of fluid. Suppression by bandaging was unbearable. His appetite was ravenous but eating became a penance because of a sore tongue and mouth which now came to stay. By day his abdomen became blown up from some 37 in. of circumference to about 43 in., and, though he never vomited or suffered much pain, the belly was skin tight. At night, when lying on his back his belly was still when he turned to the left high pitched peristalsis broke the night silence, but when he turned to the right he began serial bowel actions which lasted into the early hours. With shattering blasts of offensive wind, he would pass ten or twelve semifluid, pale, malodorous stools and his distension would subside.

In July 1946, he was admitted to the medical wards of a general hospital and retained for six months. His physicians presumed tropical sprue, or a pancreatic injury received at operation, to be the cause of his illness. When iron, liver and vitamin therapy failed, he revived to some extent on a high protein low fat diet so that by October he had little œdema and less distension. He went home failed to get the hospital diet, and relapsed immediately. A second course of inpatient treatment helped him but from his discharge in February, 1947, until his admission to the Ministry of Pensions Hospital, Ronswood, in April, 1949 he remained at home in increasing distress.

Condition on Admission

We beheld a man haggard, languid, bedridden, emaciated yet hydroptic in all his loose tissues below the neck. The soddened panniculus of the thighs could be moulded like a lump of clay retaining the imprint for an hour or more. The belly was tense with ascitic fluid and bowel wind. The skin, glossy where under watery distension, was branny and atrophic elsewhere though nowhere ulcerated or fissured and the mucocutaneous junctions were healthy. His eyes were clear of conjunctival and corneal changes and the digital extremities were undeformed. He complained bitterly of his sore tongue and mouth which were raw, beef red and fissured yet smooth between the indentations and nowhere ulcerated.

His temperature was 98.4°F, his pulse rate 72, his respiration rate 20 and his blood pressure 100/50 mm. Hg. Shortness of breath apart, he lacked pulmonary or cardiac signs and oddly enough the thoracic serous cavities were free of fluid.

No abnormality was detected in the nervous system or special senses.

At this time the time-table of his bowel actions was less systematic and he expelled about three or four pale bulky soft offensive stools in 24 hours. Periods of constipation occurred when his abdomen became even more distended, and he would then belch offensive flatus.

The Diagnosis

The assumption of sprue did not commend itself: there was no supporting history antecedent to the operation, he had never been particularly anæmic and specific therapy had failed. The presumed pancreatic injury at operation would have destroyed him forth with or led to the slow formation of a fistula or cyst. Tuberculosis might cause ascites but hardly a general anasarca, and the operation had excluded both Crohn's disease and ulcerative colitis. We discussed the possibility of low loop anastomosis but could not create it. The alternative possibility of a gastrocolic fistula was supported by his eructations with the smell of bowel wind—though gastric stagnation can generate offensive enough flatus. But to suppose that such a fistula could be due to anastomotic peptic ulceration seemed specious: for the onset had rapidly succeeded the operation and in our experience no gastrocolic fistula has led to general œdema.

economy. Not only the stomach but also the oesophagus and the saliva had become chronically and profusely infected with *Bact. coli*, and though the saliva was free of alien organisms by Sept 12 the stomach was still heavily infected four months after operation, neither had free hydrochloric acid returned, though the total acid was much lower. By January, 1950, the stomach was aseptic and free HCl was present in the secretion. On the other hand the glucose tolerance test became normal between Aug 10 and Sept 12. Not only glucose but laevulose absorption had been depressed (fig 5), a tolerance test on July 17 had shown depressed absorption of fructose, in comparison with the normal curve in tropical sprue (Maegrath et al 1945).

The reasons for the abnormal carbohydrate absorption are not clear. It persisted long after the surgical destruction of the fistula and after the patient had recovered a good measure of health, but it cleared in spite of a lusty upper alimentary infection with concomitant radiological evidence of jejunitis. Moreover, in a case of tropical sprue with characteristically disordered protein and carbohydrate absorption, we found that cultures of gastric fluid were negative.

The comparatively long persistence of achlorhydria for all functional purposes is in contrast with the appearance of hyperchlorhydria within twelve days in our cases of true gastrocolic fistulae where surgical separation without gastrectomy has been undertaken. Perhaps the presence of a large stoma for over four years causes profound, and possibly lasting, changes in the gastric mucosa. However, neither these changes nor the infection hindered

protein absorption from the time of the final operation. Perhaps the loss of the pancreatic ferment had been the deciding factor in preventing protein assimilation. Without question the oedema was nutritional according to Davis and Getzoff's (1942) classification the condition was a prehepatic hypoproteinaemia. Fig 4 illustrates the loss of weight as oedema disappeared and serum protein rose. Perhaps mechanical pressure by the anastomosis on the inferior vena cava added to the hydrops of the lower limbs.

Our conclusions on fat assimilation cannot be dogmatic, for the amount of fat in the stools was limited by the patient's inability to tolerate fat in his food. Even on his fat free diet however the quantity of fat in the stools was appreciable and the raised split/unsplitted fat ratio may signify disordered fat digestion. Hinds Howell (1945) has pointed out that in early cases of sprue the total percentage is often within normal limits whereas the split/unsplitted fat ratio may be raised above 3/1. Restoration of the normal channel, giving the food

access to the pancreatic lipase and the bile, was sufficient to correct fat absorption.

Our patient showed no deficiency in the serum-calcium and serum-phosphorus nor did he suffer from tetany. Maegrath et al. (1945) have pointed out that, though calcium absorption may be unaffected in cases of sprue syndrome in tetany, the blood-magnesium may lie between 0.75 and 1.2 mg per 100 ml. Our patient's long bones were not rarefied. In fact, the mineral metabolism observed seemed scarcely interfered with. Even the blood picture was normal.

Clinical signs of vitamin deficiency were confined to the tongue and mouth. He had a "magenta" and a psilotic tongue, and if these are signs of hyporiboflavinosis they were the only ones. Corneal and circumcorneal capillary injection were absent, but Stannus (1944) does not esteem these true signs of this particular deficiency.

Similar disorders of nutrition from mechanical causes in the alimentary tract were collected by Benker and Hammet (1939). Izod Bennett and Hardwick (1940) cast their net more widely and included coeliac disease, idiopathic steatorrhoea, tropical sprue and mechanical abnormalities of the intestinal tract under the generic title of "ileojejunal insufficiency." (To this list may be added blockage of the mesenteric lacteals—e.g., by lymphadenoma or metastatic carcinoma—which affects assimilation of fat but not of other food constituents.) Too little heed has been given to Bennett and Hardwick's paper, which collects a medley of disorders which have the same site in the wall of the small bowel, and give rise to much the same symptoms and signs. With all this resemblance, however, they may differ widely in their morbid physiology: one patient may have a normal sugar metabolism and a disordered protein assimilation with deficiency of several vitamins, while another case, clinically similar may show a quite different combination of changes. Thus Cosh (1944) and Holman (1944) describe cases of recovery from massive resection of the small bowel with quite diverse and unpredictable physiological changes.

The disastrous complications we report will be avoided if in selecting a loop of intestine for anastomosis in gastro-enterostomy (with or without gastrectomy) the surgeon makes quite sure, by inspection, that it is the highest loop of jejunum. To select a segment of bowel simply because one end of it is taut will lead, sooner or later, to selection of the terminal ileum, since both ends of the small intestine are fixed and they are less than six inches apart.

Finally it must be said that if this surgical misadventure engendered much distress, it also relieved the patient of his duodenal ulcer.

SUMMARY

In a man of 45 a grave illness suggestive of sprue dated from a gastro-enterostomy performed more than three years previously for duodenal ulcer. Laparotomies revealed that the stomach, instead of being anastomosed to the highest loop of jejunum had been joined to the ileum only 4 in. above the ileocecal valve. Virtually the whole of the small intestine had thus been excluded from the functional alimentary tract.

After a restorative operation, recovery was fairly rapid. Abnormalities in carbohydrate absorption disappeared before the gastric infection was overcome.

Many other causes can produce similar manifestations of ileojejunal insufficiency. In this variegated clinical

Fig 5—Lævulose-tolerance curve (July 15 1949)

Investigations

The gastric fluid yielded a profuse growth of *Bacterium coli*. It was bright yellow, turbid, and very offensive, and the high total acidity, with the achlorhydria, will be noted in the gruel test-meal chart (fig 1). A methylene blue enema stained the gastric fluid a very pale green, confirming the presence of a fistulous track but suggesting a narrow and perhaps a tortuous communication.

A "barium enema" showed a filling defect at the middle of the transverse colon, but no barium passed into the stomach; the film showed a general dilatation of the small bowel with fluid levels in the coils.

The film series after a "barium meal" defied interpretation. The stomach had a constant hour glass deformity. The pylorus could not be seen, but a loop of bowel, sinuous in its medial third, appeared to conform to the duodenum and the duodenojejunal flexure as it led up to the gastric stoma. Very little barium could be seen in the small bowel, which was grossly dilated with many fluid levels in the coils (fig 2). Once again radiological studies failed to demonstrate a fistulous leak from the stomach but we imagined that stomach and colon were possibly united by a narrow and irregular communication of inflammatory origin too slender to admit the barium.

Investigation of the patient's physiology in preparation for a laparotomy yielded the following results

April 24 Weight 9 st. 8½ lb
 April 25 Urine No sugar no albumin Specific gravity 1015
 Culture sterile
 April 25 Faeces Very pale, soft, offensive stool Undigested muscle fibres present. No fat globules
 Blood-count Hemoglobin, 94% erythrocytes, 5,150,000 colour index 0.91 erythrocyte sedimentation rate 1 mm in 1 hour (Westergren) no anisocytosis or polikilocytosis or hypochromia, leucocytes 6100, neutrophils 45%, lymphocytes 52%, monocytes 2% eosinophils 1%
 Serum proteins Total 4.11 g albumin 1.92 g, globulins 2.19 g per 100 ml
 Serum-calcium 8.2 mg per 100 ml
 Serum potassium, 15.5 mg per 100 ml
 Serum sodium 15.0 mg per 100 ml
 Blood urea 34 mg per 100 ml
 Wassermann and Meitnick reactions, negative
 May 13 Fat in faeces On a low fat diet the total weight of three days dried faeces was 235 g neutral fat 0.4% fatty acids 2.6%, soaps 7% and total fat 10% of dried weight, split fat 96% of total fat.
 Urinary diastase, 3 units
 Glucose tolerance (fig 3)

His weight in health had been 12 st 4 lb thus he was nearly 3 st below weight despite the tædema fluid on board.

Fig 3—Glucose-tolerance curve (April 24, 1949)

During the period between his admission and his operation he became rather worse, the serum protein and the glucose tolerance curve (fig 3) remaining depressed despite a high protein diet with folic acid and vitamins. The ascites seemed to increase in keeping with a fall of serum protein to 3.9 g per 100 ml.

Laparotomy

After preliminary blood-transfusion a laparotomy was done on May 20, 1949, using thiopentone, cyclopropane, and intercostal block.

After excising the epigastric right paramedian scar, the dense adhesions between abdominal wall, colon, stomach, and liver made access to the general coelomic cavity time consuming and laborious, but a limited approach liberated about 12 pints of clear pale ascitic fluid. The abdominal wall, omentum, and the other viscera were glassy with cedema. Assuming a gastroduodenal fistula in the dense adhesions, and as his condition began to fail, a right subhepatic defunctioning colostomy was made and the wound was closed—without getting a helpful inspection of the set-up of the abdominal viscera. The colostomy was opened forthwith.

He was unshaken by this procedure, but the colostomy produced stools of the same quality as before, and during the next week he belched wind as repelling as ever. On May 27 the colostomy failed to act and he became distended, and on the 28th he was in distress from distension though he did not vomit. The intestine was obviously obstructed.

Second Operation

At the second operation (May 28) the anæsthetic was as before, and the incision was right low paramedian. Many

pints of free fluid were removed. The small bowel throughout its length was at least 4 in in diameter and much congested. The stomach above and the cæcum below could not be found. When all the small gut was exteriorised the stomach was found behind it, anastomosed at its greater curvature to the ileum 4 in from the ileocecal valve, the stoma was 3 in long and the terminal ileum below it had a twist through 360° which almost obstructed it. The operator must have had great difficulty in forming the union, for the ileocecal bowel and the stomach were stretched across the spine and inferior vena cava to meet each other. In fact the vena cava was partly collapsed by the band of bowel.

Everything was explained the nutritional disorder by the virtual exclusion of the small intestine, the offensive eructations and the infected gastric juice by the stoma, the recurrent distension by the twisted ileal termination, the failure to vomit by the ileum above the anastomosis serving as a storehouse for food leaving the stoma until it could be forced through the narrows of the twisted bowel. The X ray appearances now bore interpretation the narrow track in the position of the duodenum was the ileocecal segment rotated and distorted on its way to the gastric stoma.

We relieved the condition by separating stomach and ileum, closing the gastric and ileal stomata, and making an ileo-ileostomy above and below the site of the stoma as seemed best under the difficult circumstances of intestinal obstruction. The stomach retracted to the upper abdomen and was not seen again, the coils of gut were deflated by needle puncture and returned to the abdominal cavity.

Progress

From now onwards this man made headway to full health. The colostomy spur was duly crushed and the fistula closed. The dropsy ebbed rapidly and could not be made out by June 20. By Aug 15 his appetite, hard to satisfy since the beginning, became voracious and it remained so during the period of recovery. He has exchanged a state of emaciation for a portly bearing, and apathy and resignation for a sanguine view of life. His stretched abdominal muscles have regained their postural tone and voluntary control, while the hydroptic distortion of his legs has left no abnormal contours behind. Within a few days the mucosa of his mouth and tongue had healed and his stools had become formed and altogether normal if a little constipated. In fact, it is remarkable that tissues and vital organs for so long the subjects of distortion, can recover so completely and so rapidly.

DISCUSSION

In this patient the signs and symptoms attributed to sprue were caused by a surgical operation which prevented food from passing through the small intestine and therefore abolished its action in digestion.

The patient's progress to recovery is portrayed graphically in fig 4. The gain in weight before his restorative operation was consonant with an increase in cedema, loss of condition, and a synchronous fall in serum protein. As the proteins returned after operation to their normal values and proportions, so the hydroptic tide ebbed and his weight fell to its minimum, but from the time when his serum was saturated he was, so to say, allowed to transfer proteins to other uses, and it was from this point that his weight increased steadily to that which he carried about in health. He needed some six weeks to accomplish this (tables I and II).

The anatomical restoration of the alimentary tract did not, however, bring a perfect return of the physiological

Fig 4—Progress towards recovery after operation

TABLE I—WEIGHT VARIATIONS, APRIL–SEPTEMBER, 1949

Date	Lb	Date	Lb
April 24	134	July 10	124

May 14	143	Aug 7	152
June 26	118	Aug 21	166
July 3	119	Sept 10	163

economy Not only the stomach but also the œsophagus and the saliva had become chronically and profusely infected with *Bact coli*, and though the saliva was free of alien organisms by Sept 12 the stomach was still heavily infected four months after operation, neither had free hydrochloric acid returned, though the total acid was much lower By January, 1950, the stomach was aseptic and free HCl was present in the secretion On the other hand the glucose tolerance test became normal between Aug 10 and Sept 12 Not only glucose but levulose absorption had been depressed (fig 5), a tolerance test on July 17 had shown depressed absorption of fructose, in comparison with the normal curve in tropical sprue (Maegraith et al. 1945)

The reasons for the abnormal carbohydrate absorption are not clear It persisted long after the surgical destruction of the fistula and after the patient had recovered a good measure of health, but it cleared in spite of a lusty upper-alimentary infection with concomitant radiological evidence of jejunitis Moreover, in a case of tropical sprue with characteristically disordered protein and carbohydrate absorption, we found that cultures of gastric fluid were negative

The comparatively long persistence of achlorhydria for all functional purposes is in contrast with the appearance of hyperchlorhydria within twelve days in our cases of true gastrocolic fistulae where surgical separation without gastrectomy has been undertaken Perhaps the presence of a large stoma for over four years causes profound, and possibly lasting, changes in the gastric mucosa However, neither these changes nor the infection hindered

TABLE II—SERUM PROTEINS (G PER 100 ML.) APRIL–SEPTEMBER, 1949

July 24	6.6	3.6	3.0
Aug 10	6.7	3.6	3.1

protein absorption from the time of the final operation Perhaps the loss of the pancreatic ferment had been the deciding factor in preventing protein assimilation Without question the œdema was nutritional, according to Davis and Getzoff's (1942) classification the condition was a prehepatic hypoproteinaemia Fig 4 illustrates the loss of weight as œdema disappeared and serum protein rose Perhaps mechanical pressure by the anastomosis on the inferior vena cava added to the hydrops of the lower limbs

Our conclusions on fat assimilation cannot be dogmatic, for the amount of fat in the stools was limited by the patient's inability to tolerate fat in his food Even on his fat-free diet however the quantity of fat in the stools was appreciable and the raised split/unsplitted fat ratio may signify disordered fat digestion Hinds Howell (1945) has pointed out that in early cases of sprue the total percentage is often within normal limits whereas the split/unsplitted fat ratio may be raised above 3/1 Restoration of the normal channel, giving the food

access to the pancreatic lipase and the bile, was sufficient to correct fat absorption

Our patient showed no deficiency in the serum-calcium and serum phosphorus, nor did he suffer from tetany Maegraith et al (1945) have pointed out that, though calcium absorption may be unaffected in cases of sprue syndrome in tetany, the blood magnesium may lie between 0.75 and 1.2 mg per 100 ml. Our patient's long bones were not rarefied In fact, the mineral metabolism observed seemed scarcely interfered with Even the blood picture was normal

Clinical signs of vitamin deficiency were confined to the tongue and mouth He had a "magenta" and a psilotic tongue, and if these are signs of hyporiboflavinosis they were the only ones Corneal and circumcorneal capillary injection were absent, but Stannus (1944) does not esteem these true signs of this particular deficiency

Similar disorders of nutrition from mechanical causes in the alimentary tract were collected by Benker and Hammet (1939) Izod Bennett and Hardwick (1940) cast their net more widely and included œsophageal disease, idiopathic steatorrhœa, tropical sprue, and mechanical abnormalities of the intestinal tract under the generic title of "ileojejunol insufficiency" (To this list may be added blockage of the mesenteric lacteals—e.g., by lymphadenoma or metastatic carcinoma—which affects assimilation of fat but not of other food constituents) Too little heed has been given to Bennett and Hardwick's paper, which collects a medley of disorders which have the same site in the wall of the small bowel, and give rise to much the same symptoms and signs With all this resemblance, however, they may differ widely in their morbid physiology one patient may have a normal sugar metabolism and a disordered protein assimilation with deficiency of several vitamins, while another case, clinically similar, may show a quite different combination of changes Thus Cosh (1944) and Holman (1944) describe cases of recovery from massive resection of the small bowel with quite diverse and unpredictable physiological changes

The disastrous complications we report will be avoided if in selecting a loop of intestine for anastomosis in gastro enterostomy (with or without gastrectomy) the surgeon makes quite sure, by inspection, that it is the highest loop of jejunum To select a segment of bowel simply because one end of it is taut will lead, sooner or later, to selection of the terminal ileum, since both ends of the small intestine are fixed and they are less than six inches apart

Finally it must be said that if this surgical misadventure engendered much distress, it also relieved the patient of his duodenal ulcer

SUMMARY

In a man of 48 a grave illness suggestive of sprue dated from a gastro enterostomy performed more than three years previously for duodenal ulcer Laparotomies revealed that the stomach, instead of being anastomosed to the highest loop of jejunum, had been joined to the ileum only 4 in above the ileocecal valve Virtually the whole of the small intestine had thus been excluded from the functional alimentary tract

After a restorative operation, recovery was fairly rapid. Abnormalities in carbohydrate absorption disappeared before the gastric infection was overcome

Many other causes can produce similar manifestations of ileojejunol insufficiency In this variegated clinical

Fig 5—Lævulose-tolerance curve (July 15 1949)

group, the clinical appearances are generally similar, but the patients may show widely different metabolic changes

Our thanks are due to the Director General of Medical Services of the Ministry of Pensions for permission to publish this case

ILEOJEJUNAL INSUFFICIENCY

AN UNUSUAL CASE OF TROPICAL SPRUE

C. F. J. CROPPER

A. M. CLARK

OBE, FRCP

MB

SENIOR PHYSICIAN

MEDICAL OFFICER

MINISTRY OF PENSIONS HOSPITAL, ROKESWOOD, WORCESTER

The following fatal case of tropical sprue had somewhat atypical features

CASE RECORD

The patient, an ex soldier aged 39, was admitted on March 10, 1949, with swelling of the legs and genitalia, slight soreness of the tongue, and loss of weight (28 lb. in twelve months)

History

Arriving in Bombay from the United Kingdom on July 27, 1945, he was treated in hospital for amoebic dysentery in August and was drafted to Hong Kong in September. In October he was again admitted to hospital, and with rest he gradually improved. He returned to this country with his unit in September, 1946, and during the voyage, like most of the troops on board, he had bowel disturbances.

The diarrhoea still present, he started work as a butcher in January, 1947, but had to give this up in March, 1948, because of swelling of the legs. He was admitted to a civil hospital and treated with 'Casydrol' by mouth and with 'Plexan' for a month. In December, 1948, he became completely bedridden with diarrhoea and swollen legs. Folic acid was given for three months, and shortly after that he came under our care.

Examination and Investigations

On admission he was passing some 12 stools daily. They were particularly foul smelling, usually watery, they often tended to be greasy and bulky but seldom gassy. His appetite was phenomenal. There was much abdominal distension with gas, but no voiding of wind or belching. His gaunt and wizened faces contrasted strongly with his bloated ascitic abdomen and grossly dropsical legs (The circumference of the calves was $15\frac{1}{2}$ in.). His tongue was congested and atrophic and fissured, but not ulcerated.

A blood count showed haemoglobin 84%, and white cells 6200 per cmm (differential white cell count normal). The stools were negative for pathogens both microscopically and on culture. The urine was free from protein, sugar, or significant deposits. A gruel test-meal showed complete achlorhydria, and the gastric contents were sterile on culture. Blood urea 28 mg per 100 ml. A glucose tolerance curve was within normal limits, with a renal threshold of 108 mg per 100 ml.

Barium meal and enema excluded gastrocolic fistula, and showed none of the fragmentation of the opaque medium reported in sprue. There was considerable dilatation of the small intestine. Sigmoidoscopy showed a moderate granularity of the mucosa only. Urinary diastase in a 24 hour specimen was 8 units per ml of urine, with a daily output of 7360 units.

Faecal fats on a low fat diet were neutral fat 5.5%, fatty acids 6.0%, soaps 24.2%, total fat 30.6% of dried weight, split fat 85% of total fat.

Course

The four months' battle against increasing inanition is

illustrated as well by the serum protein estimations as by any other figures

Date	Treatment (intravenous)	Serum albumin (g per 100 ml)	Serum globulin (g per 100 ml)
March 11	—	2.3	3.4
13	1200 ml casydrol	2.5	—
20	—	2.5	2.9
21	1800 ml casydrol	—	—
24	—	3.9	3.0
April 6	—	1.7	4.3
May 17	—	2.2	3.2
18	1200 ml blood	—	—
June 3	—	1.9	2.3
17	—	1.6	2.7
July 7	—	1.4	2.7
8	1200 ml blood	—	—
	1200 ml plasma	—	—

The level of proteinæmia seemed to us to be centre of the battle. The patient was kept strictly on Hamilton Farley's graded diets, which are high in protein and low in fat and carbohydrate contents. Starting with diet i, he proceeded steadily up to diet v, which he was taking within a fortnight of his death. Through almost the whole period, folic acid and ferrous sulphate were given in orthodox dosage, though the amount of the former was increased to 200 mg per day from July 1. It may be that parenteral folic acid, which was only then becoming available, might have had some effect.

The slow downward progress was punctuated by two untoward episodes: (1) a right middle lobe pneumonia, developing on March 16 and responding well to 'Sulphameza thine,' and (2) on April 12, typical hypocalcæmic tetany requiring 54 ml of 10% calcium gluconate intravenously to abort it. The usual measures were adopted to raise the serum calcium, and though on April 20 the level was only 4.9 mg per 100 ml no further attacks occurred.

In mid April, a three-day fat balance test was done and showed that all the ingested fat (40 g daily) was being excreted in the faeces 59% of it was split.

On July 8, the patient was noted to be looking even paler than usual, and though he apparently was not feeling unwell his blood pressure was imperceptible and his pulse rate 50 per min. The transfusions and infusions shown above were given, and there was marked improvement. Next day he was sitting up enjoying his breakfast when he suddenly became cyanosed and passed into coma, and he died within two hours.

Necropsy

Dr P. Kidd, of Worcester Royal Infirmary, reported as follows: "Gross wasting of subcutaneous tissues, with signs of dehydration. Tongue smooth and atrophic. Lungs partial collapse of both lower lobes with some purulent bronchitis. Heart myocardium flabby, valves and chambers normal. Stomach mucous membrane smooth and atrophic. Small intestine paper thin wall, almost complete absence of normal mucosal folds, atrophy of Peyer's patches. Large intestine similar changes but in lesser degree. Mesenteric glands a few calcified, no evidence of active tuberculosis. Liver normal. Spleen atrophic (weight $2\frac{1}{2}$ oz.). No other abnormalities. Cause of death inanition tropical sprue."

COMMENT

Though the frequently watery and very foul stools which were a feature of this case have been observed in sprue, they were very different from the bulky, greasy, pale, and gassy stools usually described. It was surprising to find a normal glucose tolerance curve with such gross hypoproteinæmia. Also one would have expected a greater degree of anaemia, and this was not markedly macrocytic. Finally, such extreme impairment of fat absorption as was evident here is very rarely seen. It suggested revision of our diagnosis in favour of a lymphosarcomatous or other lacteal destroying lesion.

Up to the time of necropsy, we often discussed the possibility of a gastrocolic fistula, despite the negative X-ray findings and sterile culture of gastric juice. The lack of response to "specific" measures kept us doubtful until the end.

Our thanks are due to the Director General of Medical Services of the Ministry of Pensions for permission to publish this case.

Preliminary Communication

COMPOSITION OF LIQUOR AMNII IN
HÆMOLYTIC DISEASE OF NEWBORN

THE antenatal prediction of hæmolytic disease in the children of immunised Rh negative mothers being notoriously unreliable, attempts have been made to obtain assistance from examination of the liquor amni.

If the liquor amni in late pregnancy is a mixture of fetal urine and the secretion of the amnion, in hæmolytic disease bile pigments, amino acids, or iron might possibly be found in the liquor. Liquor amni has been obtained from cases of pre eclampsia and postmaturity as well as from suspected cases of hæmolytic disease, high rupture of the membranes being used in St Mary's Hospitals, Manchester, as a method of inducing labour. Care has been taken to avoid contamination of the liquor with maternal blood, and investigations have been made within twenty-four hours of obtaining the samples. All tests have been made on centrifuged liquor.

METHODS AND RESULTS

Bile pigments—Attempts to demonstrate the presence of bile pigments with Fouchet's reagent and the van den Bergh reaction proved negative in all cases, including two in which the liquor had the characteristic golden colour seen in severe hæmolytic disease.

Urobilinogen—Tests for urobilinogen (Watson 1937) have also been negative. This does not exclude the presence of urobilinogen, since protein is thought to inhibit Ehrlich's reagent (Wilson and Davidson 1949).

Urobilin—Schlesinger's test for urobilin has also been negative in all cases.

Amino-acids—Tests for amino acids by paper chromatography have proved disappointing, because the liquor seems to contain very little amino acid. No difference has been discovered between affected and unaffected babies.

Iron—The presence of iron was first sought with the prussian blue reaction. Macroscopically this has always been negative, but the Gomori technique on dried "smears" of liquor shows that iron is always present. In cases of rhesus incompatibility the amount of iron is always increased, and the relative increase is a fairly reliable guide to prognosis. The method is, however, somewhat troublesome, and the results are not always easy to interpret. Simpler methods have therefore been sought, and the "spot reagents" produced and described by the British Drug Houses (1949) have been studied.

Tests with 'Ferron' (7-iodo-8-hydroxyquinoline 5-sulphonic acid) have been uniformly negative, indicating that the iron is present in the ferrous state.

$\alpha\alpha'$ -Dipyridyl has been tried but has not proved so satisfactory as thioglycolic acid (mercaptoacetic acid). To 5.0 ml. of liquor amni containing 1 drop of thioglycolic acid (B.D.H.) is added 0.5 ml. of ammonia (0.880), a change to purple indicates the presence of iron.

The following conclusions have been drawn from the results of 30 determinations: (1) if there is no purple, the child will be unaffected at birth but may become anæmic after the end of the first week of life, (2) if there is a faint purple, the child will be unaffected at birth but may soon become jaundiced and is almost always anæmic by the end of the first week, and (3) if there is a well marked purple, the child will be affected at birth, and the prognosis is not good.

The colour seems to be due to ionised iron in the liquor amni because the amount of iron obtained after incineration of the liquor is appreciably greater. No purple is given by meconium in solution, although this too has been shown to contain iron on incineration. No false negative

reactions have been obtained, but one false positive was found in an abortion at 16 weeks and the cause of the error is unknown.

SUMMARY

The precise origin of liquor amni is doubtful, but it certainly seems to contain some fetal urine.

A test for iron in liquor amni is described which seems to have some prognostic value, but often the hæmolytic processes are found to be too far advanced when labour is induced. Possibly, if the test were applied to liquor obtained by paracentesis in the antenatal period, the induction of labour could be timed more accurately.

Thanks are due to Prof W. I. C. Morris for suggesting that the presence of iron should be sought and for much help in the preparation of the paper.

Reviews of Books

Modern Trends in Obstetrics and Gynaecology

KENNETH BOWES M.D., M.S., F.R.C.S., obstetric physician
St. Thomas's Hospital, London. Butterworth, 1950.
Pp. 300. 60s.

A SERIES of books on Modern Trends is clearly justified, and the publishers are to be congratulated on their production of this one, which has good binding, paper, type, and illustrations. Mr. Bowes points out that the diverse researches of the past fifteen years which bear on fundamental problems of gynaecology and obstetrics make it necessary to include chapters from contributors not engaged in clinical work in this branch of medicine. He deserves much praise for the labours which have resulted in the collection of some fifty articles. They all have the same arrangement, and the main divisions and sections are prefaced by comparable type. The maternal, on the other hand, is varied in the extreme, and the value of a particular chapter depends largely on the particular reader.

Some can be assessed on the excellence of their subject-matter among these are those dealing with anatomy, pituitary trophins and steroid hormones, fetal physiology, lactation, cytology, and tuberculosis of the pelvic organs. Others will be of the greatest help to those engaged in clinical work in this category are the chapters on the rhesus factor, disproportion, anaemia, hemorrhage in pregnancy and labour, pregnancy and diabetes mellitus, tuberculosis and pregnancy, endocrine therapy, venous thrombosis, and the law in relation to obstetrics and gynaecology. This last, by Karmanski and Trevor Reeve, could usefully be read by all who practise, or hope to practise, medicine.

Many of the remaining articles evoke more mixed feelings. Those on endometriosis, abortion, radiotherapy, prolapse, toxæmias, and surgical shock are accurate and orthodox accounts which might be included in any textbook. Others deal with highly specialised and varied topics such as radioisotopes, sex and intersexuality, statistical and genetical problems, social factors and tubal motility. A few hardly seem to merit publication at all—either because the information they contain does not support the book title or because it is not generally accepted, or because it is difficult to discover. Lastly there are several articles whose value is seriously limited by their brevity. More could well be written in those concerned with psychology, heart-disease, anaemia, radiology, and urology. A new chapter on diet in pregnancy is suggested.

Naturally it is impossible that nearly fifty authors should contribute articles of equal merit, and without doubt this is a valuable first edition. The editor will presently have an opportunity to cut away some dead wood and to stimulate the growth of promising yet hesitant shoots.

group, the clinical appearances are generally similar, but the patients may show widely different metabolic changes

ILEOJEJUNAL INSUFFICIENCY

AN UNUSUAL CASE OF TROPICAL SPRUE

C. F. J. CROPPER

A. M. CLARK

OBE, FRCP, E

MB

SENIOR PHYSICIAN

MEDICAL OFFICER

MINISTRY OF PENSIONS HOSPITAL, BONESWOOD, WORCESTER

The following fatal case of tropical sprue had somewhat atypical features

CASE RECORD

The patient, an ex-soldier aged 39, was admitted on March 10, 1949, with swelling of the legs and genitalia, slight soreness of the tongue, and loss of weight (28 lb. in twelve months)

History

Arriving in Bombay from the United Kingdom on July 27, 1945, he was treated in hospital for amoebic dysentery in August and was drafted to Hong Kong in September. In October he was again admitted to hospital, and with rest he gradually improved. He returned to this country with his unit in September, 1946, and during the voyage, like most of the troops on board, he had bowel disturbances.

The diarrhoea still present, he started work as a butcher in January, 1947, but had to give this up in March, 1948, because of swelling of the legs. He was admitted to a civil hospital and treated with 'Casydrol' by mouth and with 'Plexan' for a month. In December, 1948, he became completely bedridden with diarrhoea and swollen legs. Folic acid was given for three months, and shortly after that he came under our care.

Examination and Investigations

On admission he was passing some 12 stools daily. They were particularly foul smelling, usually watery, they often tended to be greasy and bulky but seldom gassy. His appetite was phenomenal. There was much abdominal distension with gas, but no voiding of wind or belching. His gaunt and wizened facies contrasted strongly with his bloated and asoetic abdomen and grossly dropsical legs (The circumference of the calves was 15½ in.). His tongue was congested and atrophic and fissured, but not ulcerated.

A blood count showed haemoglobin 84%, and white cells 6200 per cmm (differential white cell count normal). The stools were negative for pathogens both microscopically and on culture. The urine was free from protein, sugar, or significant deposits. A gruel test-meal showed complete achlorhydria, and the gastric contents were sterile on culture. Blood urea 28 mg. per 100 ml. A glucose tolerance curve was within normal limits, with a renal threshold of 108 mg. per 100 ml.

Barium meal and enema excluded gastrocolic fistula, and showed none of the fragmentation of the opaque medium reported in sprue. There was considerable dilatation of the small intestine. Sigmoidoscopy showed a moderate granularity of the mucosa only. Urinary diastase in a 24-hour specimen was 8 units per ml. of urine, with a daily output of 7360 units.

Faecal fats on a low fat diet were neutral fat 5.5%, fatty acids 6.9%, soaps 2.2%, total fat 36.6% of dried weight, split fat 85% of total fat.

Course

The four months battle against increasing inanition is

The level of proteinæmia seemed to us to be centre of the battle. The patient was kept strictly on Hamilton Fairley's graded diets, which are high in protein and low in fat and carbohydrate contents. Starting with diet I, he proceeded steadily up to diet V, which he was taking within a fortnight of his death. Through almost the whole period, folic acid and ferrous sulphate were given in orthodox dosage, though the amount of the former was increased to 200 mg. per day from July 1. It may be that parenteral folic acid, which was only then becoming available, might have had some effect.

The slow downward progress was punctuated by two untoward episodes: (1) a right middle lobe pneumonia, developing on March 16 and responding well to 'Sulphameza-thine,' and (2) on April 12, typical hypocalcaemic tetany requiring 54 ml. of 10% calcium gluconate intravenously to abort it. The usual measures were adopted to raise the serum calcium, and though on April 20 the level was only 4.9 mg. per 100 ml. no further attacks occurred.

In mid-April, a three-day fat balance test was done and showed that all the ingested fat (40 g. daily) was being excreted in the faeces. 59% of it was split.

On July 8, the patient was noted to be looking even paler than usual, and though he apparently was not feeling unwell his blood pressure was imperceptible and his pulse rate 50 per min. The transfusions and infusions shown above were given, and there was marked improvement. Next day he was sitting up enjoying his breakfast when he suddenly became cyanosed and passed into coma, and he died within two hours.

Necropsy

Dr P. Kidd, of Worcester Royal Infirmary, reported as follows: "Gross wasting of subcutaneous tissues, with signs of dehydration. Tongue smooth and atrophic. Lungs partial collapse of both lower lobes with some purulent bronchitis. Heart myocardium flabby, valves and chambers normal. Stomach mucous membrane smooth and atrophic. Small intestine paper thin wall, almost complete absence of normal mucosal folds, atrophy of Peyer's patches. Large intestine similar changes but in lesser degree. Mesenteric glands a few calcified, no evidence of active tuberculosis. Liver normal. Spleen atrophic (weight 2½ oz.). No other abnormalities. Cause of death inanition tropical sprue."

COMMENT

Though the frequently watery and very foul stools which were a feature of this case have been observed in sprue, they were very different from the bulky, greasy, pale, and gassy stools usually described. It was surprising to find a normal glucose tolerance curve with such gross hypoproteinaemia. Also one would have expected a greater degree of anaemia, and this was not markedly macrocytic. Finally, such extreme impairment of fat absorption as was evident here is very rarely seen. It suggested revision of our diagnosis in favour of a lymphosarcomatous or other lacteal destroying lesion.

Up to the time of necropsy, we often discussed the possibility of a gastrocolic fistula, despite the negative X-ray findings and sterile culture of gastric juice. The lack of response to "specific" measures kept us doubtful until the end.

Our thanks are due to the Director General of Medical Services of the Ministry of Pensions for permission to publish this case.

Hazards of the Aged Hip

As the average age of our population increases, so does the number of fractures of the neck of the femur and the number of senile osteoarthritic hips. Moreover, thanks to chemotherapy and better technique, the old person with a damaged hip survives operation and may occupy a hospital bed for many months, thus perhaps blocking the admission of several younger patients whose restoration to full working capacity calls only for some minor surgical procedure. The result is a problem of administration as well as of surgery.

Fractured neck of femur is far commoner in women than men. There is no mystery about this: their wider pelvises expose women more to traumatic coxa vara, they are less active, they are more subject for endocrine reasons to senile osteoporosis, and above all many more reach old age (by an American estimate, the expectation of life for a woman of 60 is five times that of a man of the same age¹). Because these women usually live either alone or with a husband no longer able to care for an invalid wife, they can seldom return home until their activity is restored. Hence, as they certainly ought not to occupy surgical beds a day longer than is necessary, the obvious need is for intermediate establishments—staffed by assistant nurses or even by sensible “helpers” with a sister for stiffening—to which they can be sent soon after operation. There they could be visited regularly by the orthopaedic consultant, and they could be recalled at once to the parent centre if need arose. If operation has been performed as soon as possible after the fracture, the patient's condition is less likely to have deteriorated, with untoward developments in lungs, skin, veins, or mental state. But at present, unfortunately these cases are commonly dealt with on a weekly operating-list, for no real reason other than that most consultants live away from hospital. Where there is a resident whole time staff, as in large ex-municipal hospitals, standards of treatment are apt to be higher, and improvement could be expected from an increase in the number of specialised traumatic centres, where skilled surgery and radiography are always on hand and where the fracture can be treated as the emergency it is. We need to regard these cases as we do those of perforated ulcer, so that by next morning the patient is sitting out by her bed with the whole of the primary treatment over.

The controversy over the advisability of operating on every intracapsular fracture is settled: everyone now agrees that operation is necessary. As BOYD and GEORGE¹ remark, surveys of operative results are often somewhat discouraging, but “this does not alter the fact that internal fixation is the treatment of choice. The mortality is lower, the patient more comfortable, medical complications less frequent, senile psychosis greatly reduced, the cost of hospitalisation diminished and the percentage of bony union

greater than with any other method.” Controversy now centres rather on the treatment of trochanteric fractures, on which the debate continues because both sides can cite statistics that suit them. Thus EVANS,² comparing the results of conservative treatment with the results of fixation with a Capener Neufeld nail, concludes that routine operation has great advantages in comfort and mobility, lowered mortality, and economy in hospital beds. Reviewing 1648 reported cases he shows a mortality of 33.7% with conservative treatment against 18.3% with operation. The opposite view is taken by MURRAY and FREW,³ who plead strongly for conservative management and make the telling point that any kind of selection for operation automatically deducts the corresponding mortality from the surgical figures and adds it to the conservative total, so that a grossly unfair comparison results. They feel that “broadly speaking, any condition which can be treated equally well by operative or conservative methods should not be treated by operation.” But this ignores hospital logistics. Though intrinsically, shortage of beds is no argument for operating on a case which can be dealt with just as well otherwise, it is clear that the quicker form of treatment represents a saving in hospital days which can be used to good purpose by younger members of the community.

Concerning the purely technical aspects of inserting a Smith-Petersen pin across the intracapsular fracture, one of the best simple descriptions remains that of BANKART.⁴ VAN GORDER⁵ has reminded us that the method of reduction should be suited to the individual fracture. A routine Leadbetter or Whitman reduction is not always needed, simple traction and internal rotation by hand may be sufficient, and the powerful pull obtainable with a modern orthopaedic table may produce actual distraction which is maintained by the subsequent pinning, especially when the pin is too horizontal. To disengage the awkward small head fragment with a projecting spur on its inferior aspect, preliminary traction in adduction may be necessary. Late necrosis is especially liable to follow high fractures. An immediate osteotomy of the McMurray type—the management and mechanics of which have been well described by OSBORNE and FAHRNI⁶—would be more attractive if a really reliable method of internal fixation after osteotomy made it possible to dispense with three months in a long hip spica. Perhaps something on the lines of the “geometric osteotomy” of DICKSON,⁷ with its blade-plate fixation, might supply the answer.

In the past great respect has been paid to PAUWELS's⁸ dictum on the influence of the angle of the fracture-line on the probability of union, with its implication that in the more vertical type-III fracture bone-grafting is needed as well as pinning. Perhaps we have been too much influenced by this teaching. After all, as BANKART⁴ points out the pin's function is to convert all forces at the fracture site into vertical ones, and he aims at this by placing the pin as nearly vertical as possible and allowing early weight-bearing to compress the fragments along the pin and not in relation to the fracture-axis. BOYD and GEORGE¹ found that non union was actually rarer in type-III than in type-II cases and they point out that when the adverse shearing force has been eliminated by internal fixation there is in fact a considerably greater area of bony contact in these cases, which are usually regarded as having the worst prognosis. However this may be, it is clearly desirable to obtain as much valgus as possible by over-reduction of the fracture—the prognosis is vastly improved if the inner edge of the lower fragment can be made to project in beyond

Communicable Diseases

Editor ROSCOE L. PULLEN, M.D., F.A.C.P., professor of graduate medicine, Tulane University of Louisiana
 London Henry Kimpton 1950 Pp 1035 £7

Professor Pullen and some fifty contributors, most of whom are attached to Tulane University and the Charity Hospital of Louisiana, New Orleans, have produced a comprehensive and significant work on modern methods of diagnosis, management, treatment, and prevention of the wide range of diseases, acute and chronic, endemic and exotic, officially accepted as communicable, and usually "reportable," in the United States, the only major disease omitted deliberately is trypanosomiasis, so far not recorded in America.

Though epidemiology is discussed, especially in the accounts of the diseases which we distinguish as "tropical," the book is written primarily from the clinical standpoint. In an introductory chapter the editor deals with every aspect of the communicable diseases in general and lays stress on the changes in the management of many but by no means all of them that have been made possible by chemotherapy provided that diagnosis and the use of the appropriate chemotherapeutic agent are prompt, the period of infectivity and the duration of the illness may often be so curtailed as to permit of the patient being nursed with safety in a general ward or at home. The keynote of the book is therefore "early diagnosis," and to this end the diseases are grouped according to the main presenting symptoms and signs at the time of the initial examination. Except in the group characterised by "widespread systemic manifestations," which includes diseases as diverse as rheumatic fever and plague, this arrangement results in surprisingly little aetiological dislocation and is certainly a convenience to the practitioner. However this may be, the accounts of individual diseases are set out in orthodox textbook fashion and usually attain a high level of teaching. Outstanding is the hundred page chapter on the rickettsial diseases contributed by ten authorities including the editor.

Children, as Professor Pullen remarks, comprise the majority of patients with communicable diseases, and therefore Dr W. S. Sako has provided a compendious section on medical paediatric procedures, which, apart from its intrinsic value, serves to emphasise the fact that the fields of clinical epidemiology and paediatrics to a great extent march with each other.

This admirable work more than maintains the standards of illustration and production customary in American medical textbooks.

Supervoltage Roentgentherapy

FRANZ BUSCHKE, M.D.; SIMEON T. CANTRIL, M.D.,
 HERBERT M. PARKER, M.Sc., from the tumor institute,
 Swedish Hospital, Seattle Springfield, Ill. C. C. Thomas
 Oxford Blackwell Scientific Publications 1950
 Pp 297 77s 6d

THIS book records the experiences of the authors since 1938, using an apparatus (installed in 1932) which was designed to operate at 800 kV, and which, though the system applied is now obsolete, has continued to provide a satisfactory radiation beam. The chapters on physical considerations show the care with which dosage was measured in pressed wood models, for the evaluation of combined depth dose in multiple-field therapy, and make it possible to relate the results obtained to the doses actually delivered to the tumours.

In cancer of the mouth, lesions which were regarded as too extensive for local radium therapy could be treated with single fields because of the high depth dose and the skin tolerance at 800 kV, and the proportion of good results is satisfactory. With cervical lymphadenopathy the authors' experience was not more promising than when other forms of external irradiation were used. In the treatment of malignant tumours of the pharynx their best results have been obtained in cancer of the base of the tongue, and in other sites supervoltage was found to give no obvious advantage. It was for deep lesions, such as cancer of the oesophagus, that the high depth dose was expected to be particularly valuable, and good palliative results and an occasional cure were obtained. For the treatment of cancer of the larynx a single field approach was found to be convenient, but the results were similar to those of the usual types of treatment. Other sites dealt with are cancer of the bladder, where genuine advantages

were found, and cancer of the breast, where the use of supervoltage did not appear to be of major importance. A useful and frank chapter on cancer of the uterine cervix explains the dangers of raising large volumes of pelvic tissue to high dosage.

The conclusions reached about the use of supervoltage may seem rather pessimistic, especially in view of the comparatively small number of cases treated in each of the many sites, but the authors deserve gratitude for their objective approach and unbiased observation which must help all those at present engaged in developing supervoltage techniques.

The Hinge Graft or Ginglymus Implant

ARNOLD K. HENRY, M.B. Dubl., F.R.C.S.I., eminent professor of clinical surgery, University of Egypt, professor of anatomy, Royal College of Surgeons in Ireland
 Edinburgh E & S Livingstone 1950 Pp 64 15s

THIS is an account, written in Mr Henry's familiar style of his experiences with a novel method of bone-grafting used in the first place for the stabilisation of paralytic deformities of joints. The purpose of the hinge graft is to "guard and canalise the movements they allow." The grafts consist of "pliable strips of periosteum encrusted with bone" which are taken from the tibia and implanted in bony grooves alongside the joint. It is found that a hinge forms near the centre of movement of the joint, thus giving stability by permitting movement in one plane only.

The number of cases reviewed is small. The author describes the use of the graft in two patients with paralytic deformities of the feet, and in one with genu recurvatum. In two patients with forearm stumps an attempt was made to use a hinge graft to form a digit. In another case a hinge graft was used to replace the skeleton of a finger which had to be removed on account of bony disease.

The illustrations show that in the three patients with paralytic deformities the procedure was successful in improving stability, though deformity was not fully corrected. The hinge graft may find a place in the operative treatment of unstable joints, but in the foot a well planned and carefully executed arthrodesis should give a more satisfactory result. The attempts to form new digits or to replace the skeleton of a diseased digit were successful, though not always in the way intended.

No attempt is made to draw any conclusions, nor does Mr Henry urge the use of the hinge graft. His purpose is to describe a surgical procedure which may prove of value.

Medicine and Mankind (London Staples Press 1950 Pp 232 12s 6d).—This book was first published in 1941 and was reproduced in shorter form in 1944. It is written, it seems, for the general reader and the medical student and includes a helpful glossary of technical terms. In his preface Prof Arnold Sorsby explains that any understanding of health and disease is possible only through an approach "which visualizes the body in unstable physico-chemical equilibrium, with man, nature and the social milieu as the trinity of modern medicine." His ten chapters amplifying these views end on a note of glory in the last chapter (entitled "On the Horizon of Time"), in which man is shown to be no longer the helpless plaything of the gods but to be becoming a legislator of the universe.

Akute Infektionskrankheiten und Hochdruck (Stuttgart Thieme 1949 Pp 130 DM 9 60).—In this book Dr Otto Arnold, of Heidelberg propounds the thesis that both acute and chronic arterial disease may follow the acute infectious fevers which are often the precipitating factor of essential hypertension. He produces a series of case reports of patients who showed transitory hypertension during convalescence, emphasises that the blood pressure may be raised after scarlet fever without other evidence of nephritis and reports one or two cases in which progressive hypertension appeared to date from an acute infection. This view clearly does not explain the majority of cases of hypertension and tends to minimise the factor of heredity. Dr Arnold believes that the organism possesses certain groups of reactions to stimuli, and, while often mixing fact and theory, he appears to be striving after the conception of stress and adaptation. In linking hypertension with stress, he is now in good company.

Hazards of the Aged Hip

As the average age of our population increases, so does the number of fractures of the neck of the femur and the number of senile osteoarthritic hips. Moreover, thanks to chemotherapy and better technique, the old person with a damaged hip survives operation and may occupy a hospital bed for many months, thus perhaps blocking the admission of several younger patients whose restoration to full working capacity calls only for some minor surgical procedure. The result is a problem of administration as well as of surgery.

Fractured neck of femur is far commoner in women than men. There is no mystery about this: their wider pelvises expose women more to traumatic coxa vara, they are less active, they are more subject for endocrine reasons to senile osteoporosis, and above all many more reach old age (by an American estimate, the expectation of life for a woman of 60 is five times that of a man of the same age¹). Because these women usually live either alone or with a husband no longer able to care for an invalid wife, they can seldom return home until their activity is restored. Hence, as they certainly ought not to occupy surgical beds a day longer than is necessary, the obvious need is for intermediate establishments—staffed by assistant nurses or even by sensible “helpers” with a sister for stiffening—to which they can be sent soon after operation. There they could be visited regularly by the orthopaedic consultant, and they could be recalled at once to the parent centre if need arose. If operation has been performed as soon as possible after the fracture, the patient's condition is less likely to have deteriorated, with untoward developments in lungs, skin, veins, or mental state. But at present, unfortunately these cases are commonly dealt with on a weekly operating list, for no real reason other than that most consultants live away from hospital. Where there is a resident whole-time staff, as in large ex-municipal hospitals, standards of treatment are apt to be higher, and improvement could be expected from an increase in the number of specialised traumatic centres, where skilled surgery and radiography are always on hand and where the fracture can be treated as the emergency it is. We need to regard these cases as we do those of perforated ulcer, so that by next morning the patient is sitting out by her bed with the whole of the primary treatment over.

The controversy over the advisability of operating on every intracapsular fracture is settled: everyone now agrees that operation is necessary. As BOYD and GEORGE¹ remark, surveys of operative results are often somewhat discouraging, but “this does not alter the fact that internal fixation is the treatment of choice. The mortality is lower, the patient more comfortable, medical complications less frequent, senile psychosis greatly reduced, the cost of hospitalisation diminished and the percentage of bony union

greater than with any other method.” Controversy now centres rather on the treatment of trochanteric fractures, on which the debate continues because both sides can cite statistics that suit them. Thus EVANS,² comparing the results of conservative treatment with the results of fixation with a Capener-Neufeld nail, concludes that routine operation has great advantages in comfort and mobility, lowered mortality, and economy in hospital beds. Reviewing 1648 reported cases he shows a mortality of 33.7% with conservative treatment against 18.3% with operation. The opposite view is taken by MURRAY and FREW,³ who plead strongly for conservative management and make the telling point that any kind of selection for operation automatically deducts the corresponding mortality from the surgical figures and adds it to the conservative total, so that a grossly unfair comparison results. They feel that “broadly speaking, any condition which can be treated equally well by operative or conservative methods should not be treated by operation.” But this ignores hospital logistics. Though intrinsically, shortage of beds is no argument for operating on a case which can be dealt with just as well otherwise, it is clear that the quicker form of treatment represents a saving in hospital days which can be used to good purpose by younger members of the community.

Concerning the purely technical aspects of inserting a Smith-Petersen pin across the intracapsular fracture, one of the best simple descriptions remains that of BANKART.⁴ VAN GORDER⁵ has reminded us that the method of reduction should be suited to the individual fracture. A routine Leadbetter or Whitman reduction is not always needed, simple traction and internal rotation by hand may be sufficient, and the powerful pull obtainable with a modern orthopaedic table may produce actual distraction which is maintained by the subsequent pinning especially when the pin is too horizontal. To disengage the awkward small head fragment with a projecting spur on its inferior aspect, preliminary traction in adduction may be necessary. Late necrosis is especially liable to follow high fractures. An immediate osteotomy of the McMurray type—the management and mechanics of which have been well described by OSBORNE and FAHRNI⁶—would be more attractive if a really reliable method of internal fixation after osteotomy made it possible to dispense with three months in a long hip spica. Perhaps something on the lines of the “geometric osteotomy” of DICKSON,⁷ with its blade-plate fixation, might supply the answer.

In the past great respect has been paid to PAUWELS's⁸ dictum on the influence of the angle of the fracture-line on the probability of union, with its implication that in the more vertical type-III fracture bone grafting is needed as well as pinning. Perhaps we have been too much influenced by this teaching. After all, as BANKART⁴ points out, the pin's function is to convert all forces at the fracture site into vertical ones, and he aims at this by placing the pin as nearly vertical as possible and allowing early weight-bearing to compress the fragments along the pin and not in relation to the fracture-axis. BOYD and GEORGE¹ found that non union was actually rarer in type-III than in type-II cases, and they point out that when the adverse shearing force has been eliminated by internal fixation there is in fact a considerably greater area of bony contact in these cases, which are usually regarded as having the worst prognosis. However this may be, it is clearly desirable to obtain as much valgus as possible by over-reduction of the fracture—the prognosis is vastly improved if the inner edge of the lower fragment can be made to project in beyond

the head and support it—and DEPALMA⁹ reports encouraging results with removal of bone from the upper and outer aspect of the shaft fragment by a wedge osteotomy at open operation, so that the head can be reduced into a valgus position before pinning. Among 40 cases treated in this way there was no operative mortality, bony union followed in 90%, and necrosis in only 18%.

The problem of cancellous bone destruction on the back of the femoral neck remains as with the Colles fracture, reduction sometimes leaves a gap due to trabecular destruction which makes for redisplacement, and it might sometimes be wiser to pin the fracture in some permanent external rotation. In the light of what we now know about the influence of steroid hormones on osteogenesis and epiphyseal fusion, it would be reasonable to try more extensively the effects of these substances on bony union.

We may hope, with BOYD and GEORGE,¹ that the fractured femoral neck is no longer the "unsolved fracture", and the difficulty now is not so much to obtain union as to deal with the subsequent osteoarthritis, whether or not this develops on a basis of gross necrosis of the head. Here we touch on the problem—too often considered quite separate—of the senile osteoarthritic hip. A well-performed pseudarthrosis is excellent treatment for osteoarthritis of the hip¹⁰, yet, though fractures of the femoral neck are a far greater menace to functional recovery, we rarely see them treated in the first place by pseudarthrosis. There is, of course, reluctance to perform major open hip operations on the aged, but skilled anaesthesia, chemotherapy, and judicious transfusion nowadays enable these patients to withstand such intervention surprisingly well. The unspoken objection is to performing for a fresh fracture an operation which does not restore the anatomical status quo and which was designed to relieve a different pathological entity of slower evolution. We should, however, weigh the arthroplastic procedure, whatever it may be, not against the patient's condition before fracture (for who can guarantee to restore that?) but against the possible complications in the form of non union, arthritis, and necrosis. If this view is taken, more value may be attached to the primary treatment of suitable intracapsular fractures by some kind of arthroplasty, whether this takes the form of a pseudarthrosis—possibly stabilised by an abduction osteotomy—or of the resection reconstruction practised by the brothers JUDET,¹¹ who remove the head of the femur and replace it with an acrylic prosthesis.

Population and Food-supply

At the end of the 18th century a Surrey squire, impressed no doubt by the recent improvements in agriculture and the earliest signs of that wealth which the Industrial Revolution was later to unfold, became a disciple of GODWIN and a firm believer in the perfectibility of human society. He was wont to discuss his views with his son, and the son, with a proper suspicion of paternal opinion, examined them and came to the reverse conclusion. For, as the son argued, any temporary or local improvement in human living conditions will increase a population faster than corresponding agricultural developments can increase their food supply. Hunger and starvation, with their concomitant war and pestilence, will then automatically set back the advance and check

the population growth—these disasters are inescapable features of human society which, by its very nature, can never become stable. This argument, started in the MALTHUS family (in 1798 the son published his views in a brilliant essay),¹ continues today and is still hotly debated.

The Food and Agriculture Organisation (F.A.O.) of the United Nations attempts regularly to collect data necessary to assess the complex relations between contemporary population changes and agricultural production. CHATFIELD, SCOTT, and MAYER,² three members of the Nutrition Division of F.A.O., have set out the changes in each over the last decade, drawing their data largely from an official United Nations survey.³ It was estimated that between 1938 and 1948 the world population had gone up from 2174 to 2354 million—an increase of 8.3%. For agricultural statistics, most of Africa and the U.S.S.R. do not provide data suitable for analysis. In the remainder of the world the population, now 1777 million, has increased by 8.4%, but the figures for agricultural production, when translated into nutrients, show a corresponding increase in available calories of only 0.7% and in proteins of but 1.4%. The aggregate daily supply of available calories has fallen from 2390 per caput before the war to 2220 in 1948. The difficulties in collecting international statistics are so great that individual figures must be taken with caution, but beyond reasonable doubt there has been a fall off in the average amount of food available per head throughout the world.

In the United Kingdom the available calories have changed little, from 3000 in 1938 to 2980 in 1948. Within our country the main alteration has been in the distribution of food. It is certain that the economically unfavoured are eating more and the wealthy less today than in 1938. This levelling is a factor which leads to social stability and prevents unrest. Unfortunately in the international field there is no sign of a corresponding levelling. At the top, the U.S.A., Canada, and one or two other countries, well supplied in 1938, have more calories available per head for home consumption now. At the bottom, more and more peoples have sunk to the level of semi-starvation. Whereas formerly 22% of the total world population lived at or below the level of 2000 calories, this proportion has now risen to 35%. The increase in the inequality of distribution is the most disturbing feature of the world food picture and presents a fundamental problem in international politics, for all experience shows that in any country whose population is subsisting at the 2000 calorie level or lower political unrest is certain and civil war and disturbance an ever present threat.

CHATFIELD, SCOTT, and MAYER refuse to take sides either with the optimists or with the prophets of doom. They point out that the last decade was an abnormal one, and rightly state that it cannot be taken as a certain index of future trends. Fortunately for our temporary peace of mind, most of us are optimists and refuse to believe that periods of war are "normal".

We might, however, have difficulty in convincing *MALTHUS* *filii* that peace was the normal state of human society. Certainly, unless we contrive to manage international affairs in such a way that both agricultural production and food distribution are greatly improved, we shall be face to face with war, pestilence, and famine on the grand scale again, as he predicted. Meanwhile we can at least be grateful to the F.A.O. workers for putting the facts so concisely before us.

Gas in the Alimentary Tract

As might be expected, the distressing symptom of flatulence engaged the attention of the ancients, and *HIPPOCRATES* is said to have written at length on the "winds." Today we know quite a lot about the composition of gases in the stomach and intestine, but less about their source. The main constituents of gas in the stomach are carbon dioxide, oxygen, and nitrogen. As the gas passes down the intestinal tract the nitrogen remains unabsorbed, and other substances, such as methane and hydrogen sulphide, are added. The average volume of flatus normally passed each day has been estimated at about 0.5-1 litre,¹ with a postprandial evacuation of about 100 c.c.m.², and in one test the flatus was composed of carbon dioxide 10.3%, oxygen 0.7%, methane 29.6%, and nitrogen 59.4%.³

Gas in the intestine has been variously explained as due to fermentation of intestinal contents, diffusion of blood gases into the lumen, interference with absorption by the blood, and swallowing of atmospheric air. *MADDOCK* and his co-workers⁴ are convinced that the main source is ingested air. Normally the superior oesophageal sphincter is closed except during swallowing, but it may be relaxed consciously (by "air suckers") or unconsciously (by aerophagics), who, breathing against a closed glottis, produce a negative pressure of up to 30 cm. in the oesophagus and stomach.⁵ Deliberate repeated belching depends on knowing how to relax the superior oesophageal sphincter and then trying to breathe in with the glottis closed, the unintentional frequent belcher probably does much the same. *MADDOCK* and his associates have found that with deliberate belching the amount of air aspirated into the oesophagus was greater than the amount eructated, and so some air probably passed into the stomach. A somewhat similar mechanism accounts, they suggest, for the gastric distension sometimes accompanying the early stages of anaesthetisation. This has sometimes been attributed to repeated swallowing⁶, but in *MADDOCK*'s series of 23 cases submitted to inhalation anaesthesia for laparotomy, swallowing movements during induction averaged only 1.5. These investigators believe that relaxation of the superior oesophageal sphincter with respiratory aspiration is the cause, and they indict curare, positive-pressure anaesthesia, and obstruction of the airway as aggravating factors. They cite the case of a patient who, under sodium

thiopentone anaesthesia for a minor operation, developed an enormous pneumoperitoneum following spontaneous rupture of the stomach. This had been distended by air heard by those in the operating-theatre as it entered the oesophagus with each inspiration. As regards postoperative distension, unlike *BEGG*,⁷ who has postulated derivation of gas from the blood by "intestinal respiration," *MADDOCK* and his colleagues insist that this is traceable once again to ingested air, and they are satisfied that the colonic meteorism that may come on rapidly with retrograde pyelography is due to the same mechanism. In support of this they have confirmed *MAGNUSSON*'s⁸ observation that air may pass rapidly through the small intestine. In normal subjects ingested air was found to reach the caecum in an average of 14.6 minutes and to be passed as flatus in 24.1 minutes. In patients undergoing pyelography who were submitted to continuous gastric suction considerable volumes of air were aspirated from the stomach, and when this was kept empty, intestinal gas did not increase. Moreover, nervous patients had three times as much air aspirated from their stomachs as calm patients. These nervous patients breathed more deeply at painful stimuli, and the gas return was greatest during these periods. A previous study of normal subjects had proved that, as the depth of respiration increased, so did negative intra-oesophageal pressure and consequently the rate of aspiration of air into the oesophagus.

There is a good deal of outside evidence to support these views. Thus the efficacy of continuous gastric suction in preventing postoperative distension⁹ is most easily explained in the light of *MADDOCK*'s argument, gas appearing speedily in the upper alimentary tract of newborn infants—sometimes within 15 minutes of birth¹⁰ is most probably ingested air, and the inconspicuousness with which the laryngectomised patient collects air in his oesophagus before articulating reflects the ease with which the "air-sucker" may escape detection. A slightly different mechanism, may, however, sometimes operate. *GATCH*¹¹ has pointed out that with contraction of the abdominal muscles, relaxation of the diaphragm, elevation of the ribs, and relaxation of the superior oesophageal sphincter, a great quantity of air can rush into the stomach, and these acts, which may be performed voluntarily, explain, in his view, the ability of some to down a bottle of beer at one gulp. All the same, ingestion of air, by whatever means, does not seem to account for the excessive flatus associated with eating certain foods. *HURST*¹² maintained that in half the cases of excessive gas in the intestine the cause was fermentation due to carbohydrate dyspepsia, and that the other important cause was interference with absorption of gas by the veins of the bowel, and *ALVAREZ*¹³ asserts that sometimes gas may be excreted from the blood into the intestine. All these mechanisms may sometimes operate, but their importance in particular cases is often uncertain.

the head and support it—and DEPALMA⁹ reports encouraging results with removal of bone from the upper and outer aspect of the shaft fragment by a wedge osteotomy at open operation, so that the head can be reduced into a valgus position before pinning. Among 40 cases treated in this way there was no operative mortality, bony union followed in 90%, and necrosis in only 18%.

The problem of cancellous bone destruction on the back of the femoral neck remains as with the Colles fracture, reduction sometimes leaves a gap due to trabecular destruction which makes for redisplacement, and it might sometimes be wiser to pin the fracture in some permanent external rotation. In the light of what we now know about the influence of steroid hormones on osteogenesis and epiphyseal fusion, it would be reasonable to try more extensively the effects of these substances on bony union.

We may hope, with BOYD and GEORGE,¹ that the fractured femoral neck is no longer the "unsolved fracture", and the difficulty now is not so much to obtain union as to deal with the subsequent osteoarthritis, whether or not this develops on a basis of gross necrosis of the head. Here we touch on the problem—too often considered quite separate—of the senile osteoarthritic hip. A well-performed pseudarthrosis is excellent treatment for osteoarthritis of the hip¹⁰, yet, though fractures of the femoral neck are a far greater menace to functional recovery, we rarely see them treated in the first place by pseudarthrosis. There is, of course, reluctance to perform major open hip operations on the aged, but skilled anaesthesia, chemotherapy, and judicious transfusion nowadays enable these patients to withstand such intervention surprisingly well. The unspoken objection is to performing for a fresh fracture an operation which does not restore the anatomical status quo and which was designed to relieve a different pathological entity of slower evolution. We should, however, weigh the arthroplastic procedure, whatever it may be, not against the patient's condition before fracture (for who can guarantee to restore that?) but against the possible complications in the form of non-union, arthritis, and necrosis. If this view is taken, more value may be attached to the primary treatment of suitable intracapsular fractures by some kind of arthroplasty, whether this takes the form of a pseudarthrosis—possibly stabilised by an abduction osteotomy—or of the resection reconstruction practised by the brothers JUDET,¹¹ who remove the head of the femur and replace it with an acrylic prosthesis.

Population and Food-supply

At the end of the 18th century a Surrey squire, impressed no doubt by the recent improvements in agriculture and the earliest signs of that wealth which the Industrial Revolution was later to unfold, became a disciple of GODWIN and a firm believer in the perfectibility of human society. He was wont to discuss his views with his son, and the son, with a proper suspicion of paternal opinion, examined them and came to the reverse conclusion. For as the son argued, any temporary or local improvement in human living conditions will increase a population faster than corresponding agricultural developments can increase their food supply. Hunger and starvation, with their concomitant war and pestilence, will then automatically set back the advance and check

the population growth—these disasters are inescapable features of human society which, by its very nature, can never become stable. This argument, started in the MALTHUS family (in 1798 the son published his views in a brilliant essay),¹ continues today and is still hotly debated.

The Food and Agriculture Organisation (F.A.O.) of the United Nations attempts regularly to collect data necessary to assess the complex relations between contemporary population changes and agricultural production. CHATFIELD, SCOTT, and MAYER,² three members of the Nutrition Division of F.A.O., have set out the changes in each over the last decade, drawing their data largely from an official United Nations survey.³ It was estimated that between 1938 and 1948 the world population had gone up from 2174 to 2354 million—an increase of 8.3%. For agricultural statistics, most of Africa and the USSR do not provide data suitable for analysis. In the remainder of the world the population, now 1777 million, has increased by 8.4%, but the figures for agricultural production, when translated into nutrients, show a corresponding increase in available calories of only 0.7% and in proteins of but 1.4%. The aggregate daily supply of available calories has fallen from 2390 per caput before the war to 2220 in 1948. The difficulties in collecting international statistics are so great that individual figures must be taken with caution, but beyond reasonable doubt there has been a fall off in the average amount of food available per head throughout the world.

In the United Kingdom the available calories have changed little, from 3000 in 1938 to 2980 in 1948. Within our country the main alteration has been in the distribution of food. It is certain that the economically unfavoured are eating more and the wealthy less today than in 1938. This levelling is a factor which leads to social stability and prevents unrest. Unfortunately in the international field there is no sign of a corresponding levelling. At the top, the U.S.A., Canada, and one or two other countries, well supplied in 1938, have more calories available per head for home consumption now. At the bottom, more and more peoples have sunk to the level of semi starvation. Whereas formerly 22% of the total world population lived at or below the level of 2000 calories, this proportion has now risen to 35%. The increase in the inequality of distribution is the most disturbing feature of the world food picture and presents a fundamental problem in international politics, for all experience shows that in any country whose population is subsisting at the 2000 calorie level or lower political unrest is certain and civil war and disturbance an ever present threat.

CHATFIELD, SCOTT, and MAYER refuse to take sides either with the optimists or with the prophets of doom. They point out that the last decade was an abnormal one, and rightly state that it cannot be taken as a certain index of future trends. Fortunately for our temporary peace of mind, most of us are optimists and refuse to believe that periods of war are "normal".

diminish scouring in calves given insufficient colostrum or whey to ensure their normal growth

The hormone control of milk secretion naturally received considerable attention at the institute. It seems clear that l-thyroxine is as effective as iodinated casein as a stimulant of milk secretion. In the declining stage of lactation its administration gave increased yields up to an extra half-gallon of milk per cow per day, with increases in heart-rates up to 20 beats per minute. The main effect on composition of the milk was to increase the fat and lactose and diminish the protein, but the changes were not great. Experiments have shown that pure anterior-pituitary growth hormone has galactopoietic properties in lactating cows. The previous report from the institute that АСТН had similar properties has not been confirmed.

The bacteriology of milk, cheese, and butter has also been thoroughly studied. Progress reports of herds kept free from *Streptococcus agalactiae* illustrate both the difficulties and the possibilities of reducing bovine mastitis in this way. The antibiotic msn appears to be of considerable value in the treatment of this infection.

Naturally the institute has many collaborators, a satisfactory number of whom are also engaged in medical research. Indeed, this report might well be quoted as evidence that the distinction between medical and agricultural research is administrative rather than operational.

TOUGH TUMOUR CELLS

AN encouraging feature of experimental cancer research is that the control experiments sometimes prove unexpectedly instructive. There is an example of this in the annual report of the Yorkshire Council of the British Empire Cancer Campaign for 1949-50. Prof. R. D. Passey and Dr. L. Dmochowski, of Leeds, describe the control experiments they undertook to repair what in their view was an omission in the work reported by Gye and his colleagues¹ last year, when they showed that mouse sarcomas and carcinomas could still transmit the same type of tumour after being frozen to -79°C and desiccated to powder and subsequently thawed and reconstituted. Passey and Dmochowski confirmed these findings but could not accept the conclusion that, without controls, they necessarily indicated the presence of a virus. Gye et al. held that, judged by appearances, the drvish cells were no longer viable, despite the seemingly intact nuclei in their string-like cytoplasm. At the January meeting of the Pathological Society of Great Britain and Ireland, the Leeds critics recounted how they had dried similar mouse sarcoma tissue under the same conditions and resuspended the cells in diluent, and had now found nothing in the appearances of the cells to suggest that they were not viable. In support of their interpretation—that the cells were the source of transmission of the tumours—Passey and Dmochowski spun the resuspended cells for 3 minutes at 2600-7000 g, which would precipitate cells but not any of the known animal viruses. Thus they brought about a physical separation between diluent, which might contain virus, and cells which might be viable. Deposit and supernatant fluid were next separated and injected into mice. Tumours grew from the cell-containing fraction only. In the discussion at this meeting R. J. Ludford suggested that any remaining doubt about the viability of the cells might be removed by observing their behaviour in tissue culture. This test, promised in the present report, was subsequently performed with the assistance of I. Glücksmann of the Strangeways Laboratory, Cambridge. At the joint meeting of the pathological societies of this country

and Holland, held in Amsterdam in April, photomicrographs of outgrowing and dividing cells were shown which convinced those who saw them that some of the harshly treated cells had indeed survived and reproduced themselves even in the unfavourable conditions of tissue culture. The original experiments contained their own warning of probable disproof, for dried mammary tumours grew at the point of inoculation in connective tissues of male as well as female mice in a time interval consonant with cell grafting rather than with the action of a virus. Four other research centres² have since reported disagreement with the interpretation of Gye et al., and it has been shown that when the drying period is slightly prolonged the transmission of tumours fails.

Rabbits are proving suitable for testing chemicals that induce bladder cancer. From Sheffield Prof. H. N. Green reports the induction of one ureteric tumour in a rabbit within about 2 years of feeding with acetylaminofluorene. Dr. G. Bonser, in Leeds, has induced one bladder tumour and one ureteric papilloma, besides other changes suggestive of malignancy, within 5 years with the same chemical. She has promising experiments on hand with betanaphthylamine. If rabbits respond to both carcinogens by developing tumours of the urinary tract, this animal will have advantages over the dog in ease of handling and cheapness, though none in point of time. Mice respond only to the first compound and many develop hepatomas as well. The rabbit tumours are limited to the urinary tract.

Statistical inquiries into the inheritance of mammary cancer in this country have yielded no evidence that the incidence was any greater among 584 mothers of patients with this disease than among the same number of unselected women in the general population. This result, checked by the evidence of breast tumours in living daughters and by the death certificates of the mothers, conflicts with observations reported from the Continent which suggest that there is some familial association. Examination of human milk by electron microscopy for evidence of an infective milk agent analogous with Bittner's agent in mice is proceeding but has not yet reached a reportable stage.

GENERAL PRACTICE IN NORTHERN IRELAND

THE Northern Ireland committee of the Nuffield Provincial Hospitals Trust has decided to make an independent survey of the conditions of general practice in the region. The main objects are to improve the status of the general practitioner and to find, if possible, how he can obtain reasonable time for leisure, contact with his colleagues, and postgraduate study. The assumption is that any improvement which can be made on these lines will be reflected in improved service to the patient. Dr. J. A. Fisher, formerly of the Nuffield Department of Clinical Medicine, Oxford, has been appointed to make the survey, which will be based on sample surveys, questionnaires, and direct interviews with the practitioners. Although the Nuffield survey is independent, it is being made with the approval and encouragement of the North Ireland Ministry of Health, the Health Services Board, and other interested authorities in the region.

THE INDEX and title-page to Vol. I, 1950, which was completed with THE LANCET of June 24, is now in preparation. A copy will be sent gratis to subscribers on receipt of a postcard addressed to the Manager of THE LANCET, 7, Adam Street, Adelphi, W.C.2. Subscribers who have not already indicated their desire to receive indexes regularly as published should do so now.

POTENTIATION OF SULPHONAMIDES

THE paper by Professor Bigger and Mr Ware which we publish this week is unhappily the last of the series reporting the senior author's investigations on antibacterial substances. They began with an article appearing in 1944¹ in which he described the synergic action of penicillin and sulphonamides. This was quickly followed by one describing inactivation of penicillin by serum,² and a third in the *Irish Journal of Medical Science*³ which conclusively demonstrated the bactericidal action of penicillin. These contributions resulted from work done in the Command Laboratory at York, where Professor Bigger served during the late war as assistant director of pathology, Northern Command, and they illustrate both his love of inquiry and his determination to go on inquiring in circumstances which others might think inconvenient for fundamental research. During the same difficult period he also made contributions on impetigo⁴ and on jaundice in syphilis⁵.

Though some of his research on antibacterial substances might seem academic, Professor Bigger never hesitated to suggest how the principles might be applied to clinical practice, in fact, he laid down schemes for the treatment of staphylococcal infections⁶ and typhoid carriers⁷ using these agents. On his return to Dublin after the war the scope of his studies was enlarged, and many of the antibacterial substances in general clinical use were tested at varying concentrations and in different combinations to ascertain whether they showed antagonism or were synergistic⁸. In the current paper Bigger and Ware tell how, in an attempt to overcome the well known antagonising effect of broth on sulphonamides, a synthetic medium was used to which a little 'Lab Lemco' was added, and this led to the discovery that lab lemco contains a substance which, though not itself antibacterial, enables sulphonamides to kill micro organisms instead of merely inhibiting their growth. This type of reaction Bigger calls potentiation, and he records the investigation designed to elucidate its nature. A start has already been made to isolate the substance (termed L substance) concerned, and no doubt the work will continue on Professor Bigger's original impetus. But all must greatly regret, on scientific as well as personal grounds, that the end of this week sees his retirement, through ill health, from the Dublin chair of bacteriology he has so ably filled.

PRODUCTION OF ANTIBIOTICS

IN some countries the construction of efficient plants for the manufacture of antibiotics is being hampered by difficulty in obtaining essential equipment, such as Podbielniak extractors for penicillin production. At its first meeting, in Geneva last April, the W H O Expert Committee on Antibiotics concluded that with existing knowledge these extractors could not be used to concentrate toxins for bacteriological warfare, and it declared that the prestige of W H O had been seriously damaged by its inability to help various governments to lay hands on this apparatus. There was no recent information on the state of the UNRRA penicillin plants in the Byelorussian S S R, China, and the Ukrainian S S R, but if W H O were approached, the committee would gladly consider any problems that had arisen.

- 7 Bigger J W Daly, R A *Ibid* 1949 I 296
- 8 Bigger J W *Ibid* July 8 1950 p 46

Those attending the meeting were Prof E B Cham, FRS (Italy), Prof R V Christie, Prof M M Janot (France), Prof H Theorell (Sweden), and Prof S A Waksman (U.S.A.). The report on their deliberations, which has only just reached us, observes that often the most serious obstacle to increased production is lack of trained personnel, and recommends that W H O research fellowships should be founded to enable people with a sound knowledge of chemistry, engineering, or microbiology to attend for a year or more at selected institutes. Help in constructing new plants should be given to as many countries as possible. The risk of firms losing capital through a particular antibiotic becoming obsolete is negligible, since the equipment can be modified for the manufacture of others. Recognising the investigator's difficulty in surveying the whole field of antibiotic research, the committee decided to explore the possibility of setting up a rapid and comprehensive abstracting service. It also discussed the advisability of holding next year a symposium on one or more aspects of antibiotics, and a larger congress in 1952.

DAIRY RESEARCH IN READING

THE national policy of an abundance of home produced milk is ably supported by the team of close on 80 scientific research-workers at the National Institute for Research in Dairying (N I R D) at the University of Reading. In 1949 they published 58 papers on the subject and their report¹ displays the astonishing diversity of the problems connected with the production, distribution, and manufacture of milk and its products. In view of our need to restrict imports of winter feeding stuffs for cows it is satisfactory to learn that well managed leys showed a good capacity to produce milk throughout the year and that there is every reason for exploiting them to the maximum. To many it has seemed that we were in danger of forgetting that grass is the natural food of cows and to have been slow in this country to follow the lead from New Zealand and develop experiments on pasture management under our own special conditions as an essential part of our research into animal nutrition. A possible explanation is the difficulty of combining experimental work with some aspects of farm management, and the N I R D is prepared to face this reality. Another encouraging development of the same problem is the work done on the value of kale, cabbage, maize silage, and fodder beet for winter feeding. It appears that fodder beet may be practically useful for the small holder especially since it may be used to feed pigs.

It is evident from the report that fundamental and applied research can thrive well together, each gaining something from the proximity of the other. The sections dealing with the nutritional rôle of the micro organisms of the intestinal tract indicate how much has yet to be learnt about this subject in spite of all the work and writing. For instance, one sample of potato starch given to rats on a diet deficient in vitamin B enabled the animals to survive and grow—the phenomenon known as refection—whereas another sample did not. It is noteworthy that refected rats, even when given supplements of the known B vitamins, could produce only small litters and were unable to suckle them. Above a certain concentration, B vitamins may be directly absorbed from the rumen of the goat, and enough biotin is present in the rumen liquor of a cow to permit of its direct absorption.

The protective effect of colostrum against white scours in calves is now well established, and this property has been found to reside in the non dialysable constituents of whey. Treatment with sulphaguanidine did not

1 University of Reading National Institute for Research in Dairying Report for the year 1949

diminish scouring in calves given insufficient colostrum or whey to ensure their normal growth

The hormone control of milk secretion naturally received considerable attention at the institute. It seems clear that *L-thyroxine* is as effective as iodinated casein as a stimulant of milk secretion. In the declining stage of lactation its administration gave increased yields up to an extra half gallon of milk per cow per day, with increases in heart-rates up to 20 beats per minute. The main effect on composition of the milk was to increase the fat and lactose and diminish the protein, but the changes were not great. Experiments have shown that pure anterior pituitary growth hormone has galactopoietic properties in lactating cows. The previous report from the institute that ACTH had similar properties has not been confirmed.

The bacteriology of milk, cheese, and butter has also been thoroughly studied. Progress reports of herds kept free from *Streptococcus agalactiae* illustrate both the difficulties and the possibilities of reducing bovine mastitis in this way. The antibiotic nisin appears to be of considerable value in the treatment of this infection.

Naturally the institute has many collaborators, a satisfactory number of whom are also engaged in medical research. Indeed, this report might well be quoted as evidence that the distinction between medical and agricultural research is administrative rather than operational.

TOUGH TUMOUR CELLS

AN encouraging feature of experimental cancer research is that the control experiments sometimes prove unexpectedly instructive. There is an example of this in the annual report of the Yorkshire Council of the British Empire Cancer Campaign for 1949-50. Prof. R. D. Passey and Dr. L. Dmochowski, of Leeds, describe the control experiments they undertook to repair what in their view was an omission in the work reported by Gye and his colleagues¹ last year, when they showed that mouse sarcomas and carcinomas could still transmit the same type of tumour after being frozen to -79°C and desiccated to powder and subsequently thawed and reconstituted. Passey and Dmochowski confirmed these findings but could not accept the conclusion that, without controls, they necessarily indicated the presence of a virus. Gye et al. held that, judged by appearances, the dryish cells were no longer viable, despite the seemingly intact nuclei in their string-like cytoplasm. At the January meeting of the Pathological Society of Great Britain and Ireland, the Leeds critics recounted how they had dried similar mouse sarcoma tissue under the same conditions and resuspended the cells in diluent, and had now found nothing in the appearances of the cells to suggest that they were not viable. In support of their interpretation—that the cells were the source of transmission of the tumours—Passey and Dmochowski spun the resuspended cells for 3 minutes at 2600-7000 g, which would precipitate cells but not any of the known animal viruses. Thus they brought about a physical separation between diluent, which might contain virus, and cells which might be viable. Deposit and supernatant fluid were next separated and injected into mice. Tumours grew from the cell-containing fraction only. In the discussion at this meeting, R. J. Ludford suggested that any remaining doubt about the viability of the cells might be removed by observing their behaviour in tissue culture. This test, promised in the present report, was subsequently performed with the assistance of I. Glücksmann of the Strangeways Laboratory, Cambridge. At the joint meeting of the pathological societies of this country

and Holland, held in Amsterdam in April, photomicrographs of outgrowing and dividing cells were shown which convinced those who saw them that some of the harshly treated cells had indeed survived and reproduced themselves even in the unfavourable conditions of tissue culture. The original experiments contained their own warning of probable disproof, for dried mammary tumours grew at the point of inoculation in connective tissues of male as well as female mice in a time interval consonant with cell grafting rather than with the action of a virus. Four other research centres² have since reported disagreement with the interpretation of Gye et al., and it has been shown that when the drying period is slightly prolonged the transmission of tumours fails.

Rabbits are proving suitable for testing chemicals that induce bladder cancer. From Sheffield Prof. H. N. Green reports the induction of one ureteric tumour in a rabbit within about 2 years of feeding with acetaminofluorene. Dr. G. Bonser, in Leeds, has induced one bladder tumour and one ureteric papilloma, besides other changes suggestive of malignancy, within 5 years with the same chemical. She has promising experiments on hand with betanaphthylamine. If rabbits respond to both carcinogens by developing tumours of the urinary tract, this animal will have advantages over the dog in ease of handling and cheapness, though none in point of time. Mice respond only to the first compound and many develop hepatomas as well. The rabbit tumours are limited to the urinary tract.

Statistical inquiries into the inheritance of mammary cancer in this country have yielded no evidence that the incidence was any greater among 584 mothers of patients with this disease than among the same number of unselected women in the general population. This result, checked by the evidence of breast tumours in living daughters and by the death certificates of the mothers, conflicts with observations reported from the Continent which suggest that there is some familial association. PRODUCTION OF ANTIBIOTICS

IN some countries the construction of efficient plants for the manufacture of antibiotics is being hampered by difficulty in obtaining essential equipment, such as Podbielmak extractors for penicillin production. At its first meeting, in Geneva last April, the W H O Expert Committee on Antibiotics concluded that with existing knowledge these extractors could not be used to concentrate toxins for bacteriological warfare, and it declared that the prestige of W H O had been seriously damaged by its inability to help various governments to lay hands on this apparatus. There was no recent information on the state of the UNRRA penicillin plants in the Byelorussian S S R, China, and the Ukrainian S S R, but if W H O were approached, the committee would gladly consider any problems that had arisen.

Those attending the meeting were Prof E B Chan, F R S (Italy), Prof R V Christie, Prof M M Janot (France), Prof H Theorell (Sweden), and Prof S A Waksman (U.S.A.). The report on their deliberations, which has only just reached us, observes that often the most serious obstacle to increased production is lack of trained personnel, and recommends that W H O research fellowships should be founded to enable people with a sound knowledge of chemistry, engineering, or microbiology to attend for a year or more at selected institutes. Help in constructing new plants should be given to as many countries as possible. The risk of firms losing capital through a particular antibiotic becoming obsolete is negligible, since the equipment can be modified for the manufacture of others. Recognising the investigator's difficulty in surveying the whole field of antibiotic research, the committee decided to explore the possibility of setting up a rapid and comprehensive abstracting service. It also discussed the advisability of holding next year a symposium on one or more aspects of antibiotics, and a larger congress in 1952.

DAIRY RESEARCH IN READING

THE national policy of an abundance of home produced milk is ably supported by the team of close on 80 scientific research-workers at the National Institute for Research in Dairying (N I R D) at the University of Reading. In 1949 they published 58 papers on the subject, and their report¹ displays the astonishing diversity of the problems connected with the production, distribution, and manufacture of milk and its products. In view of our need to restrict imports of winter feeding stuffs for cows it is satisfactory to learn that well managed leys showed a good capacity to produce milk throughout the year and that there is every reason for exploiting them to the maximum. To many it has seemed that we were in danger of forgetting that grass is the natural food of cows and to have been slow in this country to follow the lead from New Zealand and develop experiments on pasture management under our own special conditions as an essential part of our research into animal nutrition. A possible explanation is the difficulty of combining experimental work with some aspects of farm management, and the N I R D is prepared to face this reality. Another encouraging development of the same problem is the work done on the value of kale, cabbage, maize silage, and fodder beet for winter feeding. It appears that fodder beet may be practically useful for the small holder especially since it may be used to feed pigs.

It is evident from the report that fundamental and applied research can thrive well together, each gaining something from the proximity of the other. The sections dealing with the nutritional rôle of the micro organisms of the intestinal tract indicate how much has yet to be learnt about this subject in spite of all the work and writing. For instance, one sample of potato starch given to rats on a diet deficient in vitamin B enabled the animals to survive and grow—the phenomenon known as refection—whereas another sample did not. It is noteworthy that refected rats, even when given supplements of the known B vitamins, could produce only small litters and were unable to suckle them. Above a certain concentration, B vitamins may be directly absorbed from the rumen of the goat, and enough biotin is present in the rumen liquor of a cow to permit of its direct absorption.

The protective effect of colostrum against white scours in calves is now well established, and this property has been found to reside in the non dialysable constituents of whey. Treatment with sulphaguandine did not

the professional workers as much as possible of non-professional and non-technical duties; to provide, then, the facilities and machinery by which the fullest expression of functions may most easily be obtained."

4. *The administrative authority was normally vested in the governing body, which would meet perhaps quarterly, and between meetings a very large measure of that authority would be delegated to a smaller body and to certain officers*

The fact that these officers—usually the chairman (or treasurer) and the "clerk" or latterly the house-governor—were entrusted with considerable power to act in the name of the governing body greatly facilitated the smooth running of the institution.

The part played by the committee is largely traditional, and scarcely admits of precise definition. A good description is that contained in an American textbook in 1913

"The best conducted institution of whatever kind will be that in which the members of a board of directors are large and broad men and women, or both, who will insist upon the selection of the right sort of executives—a board that can and will encourage all of its officers to do their utmost for the common good that will encourage all the facts in the institution to work in harmony with a common helpfulness. . . The crying need is for men and women who will take a personal interest. This does not mean that a board of directors should divide itself up into committees to look after the janitors and housework, or to run the training school, or to tell the members of the medical staff how to treat their patients, too many boards of directors contain just such members—members who have plenty of time on their hands, but very little else to give to the institution, who have little influence in the community who have less judgment, and who eventually earn the wholesome contempt of those who have to do the real work in the institution—that is, the salaried employees."

5. *A most important modification of the tradition was effected by Florence Nightingale when she got it established that hospitals were in fact better run if the matron were admitted as a third party to the partnership between lay authority and medical staff, and if the nursing of the patients and the domestic arrangements most closely connected therewith were entrusted to her care*

Having appointed a matron, the lay administration may no more give direction affecting matters entrusted to her care than they may interfere in the medical treatment of a patient by a member of the medical staff. Other departments have since grown up and matrons have been relieved of some of the responsibility—notably catering—which they inherited from the Nightingale era—but these changes scarcely affect the central issue. The newer departments can be grouped under one or other of the three heads

Current British practice offers examples of all degrees of responsibility ranging from something very like the pre-Nightingale, where the matron is subordinate to the medical officers, to the full Nightingale conception wherein the matron is "mistress of the household", and back again to a more recent phase in which the matron has discarded some of her less strictly nursing responsibilities. At the same time her responsibilities in other directions—particularly recruitment—have become much heavier.

Lay committees are apt to assume that because the matron is appointed by them it is proper for them to expect her to be answerable to them on all sorts of matters. This is certainly contrary to the central tradition—once having appointed the matron the governing body leave it to her to exercise her judgment in much the same sense as they leave the medical care of the patients to the medical staff.

6. *Since Florence Nightingale's time the hospital in the central tradition has been essentially a tripartite organisation—administration (with which financial control is inextricably bound up) acting in concert with the medical staff and with the matron and*

nursing staff. Harmony depends on a recognition by all parties of the extent and limits of their respective responsibilities

The pressure from the medical staff for ever greater facilities is a dominant factor, and it is a primary function of the governing body of the hospital to sift the wheat from the chaff, to guide and control this pressure in the light of its limited resources.

It should now be possible to see in outline what were the main component parts of a hospital as understood in the British voluntary hospital tradition. It is perhaps a misfortune that almost all the textbooks dealing with hospital administration emphasise the physical construction and equipment of the hospital, with the result that the reader is taken on a kind of Cook's tour of the departments, wards, kitchens &c., before being shown, if he ever is shown, how the model works.

A clear understanding of functions will often enable a comparative novice to see what is wrong when a hospital is in trouble. Sometimes it is that the medical staff have allowed themselves to become confused as to their advisory status in regard to the management, or about the right way of making their influence felt, sometimes it is that the governing body do not appreciate the underlying contract into which they enter when they appoint a matron.

A proper appreciation of the tensions and strains involved will help the administrator to know what to expect. It is obvious that it is not to be expected that the day will pass without someone being upset about something when human frailty is superadded to an already complicated pattern of relationship. Very much depends therefore on the way in which this stress is absorbed by the administration.

THE LOCAL-AUTHORITY PATTERN

Besides the tradition here described as "central," there has existed another tradition developed by the publicly owned hospitals during the 19th century, characterised by two things

1. *The resting of administrative and financial control of the hospital in an authority separate and distinct from the hospital itself and often discharging functions unrelated to the hospital*
2. *The resting of clinical responsibility for all the patients in the hospital in a medical superintendent, latterly supported by a considerable subordinate medical staff*

The pattern has been adopted, often very successfully, for certain special types of institution—mental hospitals, sanatoria for tuberculosis, and so on. By reason of the circumstances of its origin it has many affinities in Continental hospital systems maintained at the public expense. A similar system has also been developed in America in the publicly provided hospitals.

It must be noted, however, that in this latter pattern

3. *The clinical responsibility vested in the medical superintendent has precluded the development of a consultant medical staff with clinical responsibility for the patients under their care as underdeveloped in the voluntary hospitals of Great Britain and America*

and further that

4. *The position of the matron was radically different from that in a hospital where the Nightingale principle was accepted in full. Where the medical superintendent carried clinical responsibility the matron normally accepted his authority as covering the whole medical-nursing field (with the exception of the arrangements in connection with nurse training schools)*

THE BEST OF BOTH WORLDS

It is not the purpose of these notes to discuss the relative merits of the two patterns for that would carry the discussion far afield. The hospitals of the two

PREFACE TO HOSPITAL ADMINISTRATION

(FROM A CORRESPONDENT)

MANY minds are being applied to problems of hospital administration. The King's Fund, in concert with the Institute of Hospital Administrators, has announced the opening in the autumn of a Hospital Administrative Staff College. Recently the Ministry of Health has set up a Committee on the Internal Administration of Hospitals, itself distinct from the Committee on Hospital Administration appointed a year or more ago. What is the proper relationship of the administrative and financial sides? What part should medical men play in administration? Is it possible to work out anything like an agreed pattern for the hospital management committee, so that effective comparison could be made between one establishment and another?

Background

Much of the discussion is rendered ineffective by lack of a common conception of the background. The popularly accepted outlook is in many respects sadly deficient. Too often it amounts to little more than the belief that before the appointed day there were two sorts of hospitals, voluntary and local authority, the voluntary hospitals were individualistic and selected their cases to suit their medical staffs, but, despite their part dependence on charity, they mostly reached a reasonably high standard of comfort for the patients, except in the matter of the long waits for outpatients and the early waking hours, while the local authority hospitals were large institutions, which on the whole were far more short of nurses than the voluntary hospitals but nevertheless managed to make a pretty good job of it, and in particular could teach the voluntary hospitals a good deal about the duty of a hospital to take in old people and other difficult types of case. To this is added the idea that now that the hospitals are nationalised it is up to the boards and committees to take charge, and that the medical and nursing staff are now, like it or not, "employees."

Now mental pictures of this kind may be fairly accurate as far as they go, but they are wholly inadequate as a basis for discussions, the object of which is to settle the pattern of hospital administration for the next generation. They fail to make clear what is the function of the administrative authority, and what is its relationship with the professional medical and nursing staff and how the main components fit together. It was a partial failure of this kind which led to lapses in the Ministry's early hospital management committee circulars which have caused anxiety and difficulty, and if it is repeated again in the discussions now being undertaken the danger will be equally serious.

It is necessary to get a clear grasp of the principles of hospital administration, and to understand the relationship of the governing body and the medical and nursing staff. This relationship is traditional, it is nowhere defined in the Act or elsewhere, and a faulty appreciation of what is involved is by far the commonest source of friction in hospital affairs. It is therefore most important to get a clear grasp of the central pattern and the variants upon it. The subject has never been adequately handled, apart from the hints contained in Florence Nightingale's brief but famous appendix to her *Notes on Hospitals*.

THE CENTRAL PATTERN

First let us take the main British hospital tradition of the last 200 years—i.e., that of the voluntary hospitals

The historic practice evolved in the voluntary hospitals was for the responsible medical work to be entrusted to a number of physicians, surgeons, &c., who jointly comprise the medical staff of the hospital. Each had a group of beds for which he is held responsible. It is well understood that he does not interfere in the treatment of cases assigned to another member of the staff unless he is asked to do so.

2 *The medical staff have carried definite responsibilities for tendering advice to the administrative authority in regard to the management of the hospital, and this advice has been canalised through the medical committee*

The medical committee is (in words borrowed from a speech by Lord Moran in the House of Lords) as a general rule composed of all the senior staff. In a large hospital, some thirty, forty, or fifty men may sit on this committee. It is their duty to keep their colleagues informed of any new equipment or development of knowledge wherever it may occur all over the world, and some of them sit on the management committee and try to convince the committee that this or that should be done. The arrangement serves a double purpose. It is a guarantee that new projects (and they are legion) before reaching the governing body have first run the gauntlet of criticism and discussion in the medical committee, and it sets the governing body itself free from the futility of spending its time listening to endless debates among the medical men. Even in the older hospitals where the tradition is clearest, there were many different ways of achieving the general result above described. For example, in some hospitals no members of the medical staff sat upon the governing body and consultation was achieved by means of a small joint subcommittee. In others, too many of the medical staff were given seats on the governing body, and the balance was thereby upset.

3 *The main function of the administration has been the enlightened pursuit of economy, "so far as it is consistent with the requirements of the sick."*

It is not too much to say that in hospital terminology that is what is meant by administration. "Administration," wrote Florence Nightingale, "is intended to enforce economy as far as it is consistent with the requirements of the sick", elsewhere she speaks of the function of the administration as the "general discipline and control of expenditure." It is true that the words have a negative, discouraging ring and that since her day the range of interests required of a hospital administrator have been widened out of all recognition. They are, nevertheless, a corrective to the now popular idea that the administrator can relegate the pursuit of economy to the finance officer and concern himself with the rest of the work.

If administration is the pursuit of economy, what does economy mean? The word has a wide range of meaning and is the source of much confusion in the hospital world. In its true original sense it means the best working of the hospital within the limits of its resources—"value for money", in its other, and perhaps more common usage, it is twin sister to "cheese paring." The outsider who is little instructed in hospital affairs is very ready to invoke the need for economy, and to believe that the efficiency of the hospital can best be tested by little matters—the care taken about the pig-swill is a favourite example. It is, of course, important to be careful about the pig swill, but it is more important to realise that economy goes much deeper than this and affects the whole range of hospital administration. "The chief function of administration," wrote Dean Rappleye in a report to the Rockefeller Foundation in 1922, "is to create an environment conducive to the spontaneous, creative expressions of the groups working within the organisation and to relieve

1 *A sharp distinction has been drawn between the clinical responsibility of the medical staff for the treatment of their patients and their advisory status in regard to the administration of the hospital*

the professional workers as much as possible of non-professional and non-technical duties, to provide, then, the facilities and machinery by which the fullest expression of functions may most easily be obtained"

4 *The administrative authority was normally vested in the governing body, which would meet perhaps quarterly, and between meetings a very large measure of that authority would be delegated to a smaller body and to certain officers*

The fact that these officers—usually the chairman (or treasurer) and the "clerk" or latterly the house governor—were entrusted with considerable power to act in the name of the governing body greatly facilitated the smooth running of the institution

The part played by the committee is largely traditional, and scarcely admits of precise definition. A good description is that contained in an American textbook in 1913

It is therefore most important to get a clear grasp of the central pattern and the variants upon it. The subject has never been adequately handled, apart from the hints contained in Florence Nightingale's brief but famous appendix to her *Notes on Hospitals*.

THE CENTRAL PATTERN

First let us take the main British hospital tradition of the last 200 years—i.e., that of the voluntary hospitals.

- 1 A sharp distinction has been drawn between the clinical responsibility of the medical staff for the treatment of their patients and their advisory status in regard to the administration of the hospital.

The historic practice evolved in the voluntary hospitals was for the responsible medical work to be entrusted to a number of physicians, surgeons, &c., who jointly comprised the medical staff of the hospital. Each had a group of beds for which he is held responsible. It is well understood that he does not interfere in the treatment of cases assigned to another member of the staff unless he is asked to do so.

- 2 The medical staff have carried definite responsibilities for tendering advice to the administrative authority in regard to the management of the hospital, and this advice has been canalised through the medical committee.

The medical committee is (in words borrowed from a speech by Lord Moran in the House of Lords) as a general rule composed of all the senior staff. In a large hospital, some thirty, forty, or fifty men may sit on this committee. It is their duty to keep their colleagues informed of any new equipment or development of knowledge wherever it may occur all over the world, and some of them sit on the management committee and try to convince the committee that this or that should be done. The arrangement serves a double purpose. It is a guarantee that new projects (and they are legion) before reaching the governing body have first run the gauntlet of criticism and discussion in the medical committee and it sets the governing body itself free from the futility of spending its time listening to endless debates among the medical men. Even in the older hospitals where the tradition is clearest, there were many different ways of achieving the general result above described. For example, in some hospitals no members of the medical staff sat upon the governing body and consultation was achieved by means of a small joint subcommittee. In others, too many of the medical staff were given seats on the governing body, and the balance was thereby upset.

- 3 The main function of the administration has been the enlightened pursuit of economy, "so far as it is consistent with the requirements of the sick."

It is not too much to say that in hospital terminology that is what is meant by administration. "Administration," wrote Florence Nightingale, "is intended to enforce economy as far as it is consistent with the requirements of the sick", elsewhere she speaks of the function of the administration as the "general discipline and control of expenditure". It is true that the words have a negative, discouraging ring and that since her day the range of interests required of a hospital administrator have been widened out of all recognition. They are, nevertheless, a corrective to the now popular idea that the administrator can relegate the pursuit of economy to the finance officer and concern himself with the rest of the work.

If administration is the pursuit of economy, what does economy mean? The word has a wide range of meaning and is the source of much confusion in the hospital world. In England Now

A Running Commentary by Peripatetic Correspondents

MY shaggy blue roan cocker bitch (who is not so damn' shaggy as all that) did not display her usual enthusiasm when invited to come and walk partridges with me on Saturday. "Of course, I'd love to come," she cooed in her mincing Cambridge accent, "but *actually* I've got the most fearful rheumatism in my off hind"—and she limped around on three legs wagging the rest of herself, a well known technique employed to excite sympathy. I examined the limb but was unable to elicit any abnormal physical signs. "You'd better come," I suggested, "you'll enjoy the ride and you needn't hunt if you don't want to." Protesting genteelly she allowed herself to be lumped into the car. Arrived at the farm where we shoot, I helped her out and started to walk across a rough field. Looking like a martyr, she limped dutifully behind. Presently we put up a rabbit. "Look, look, look!" she screamed and gave chase, as she always does, despite all my rating and whistling. As usual the rabbit made the hedge safely with a dozen yards to spare and she came bounding back. "What about that rheumatism?" I asked. She made no reply but proceeded to quarter the field on four legs as thoroughly as ever. We've heard no more about it. Functional, you see.

* * *

The Peripatetic Pathologist from Portsmouth, who ministered to the needs of the lady in the train soon after it left Grand Central Station, had a much easier time than I did on my way to Rome just after the war. The Paris-Milan-Rome express was not yet restored to its pre-war comfort and "Mussolinian efficiency" and I had spent the last few hours wondering how late we would arrive in Rome—would we be 16 or 20 hours behind schedule?

My companion, who believed in comfort at all times, was in a foul temper, and trying hard to get some much needed beauty-sleep, when the guard came down the corridor, asking if there was a doctor on the train. Once before, in my early enthusiastic days, I had got into an unfortunate position by bounding forward when such a cry was raised, so I cringed back in the darkest corner of the compartment. When the guard had gone by, my companion rounded on me and scornfully demanded why I didn't help. I was trying to explain when the guard returned up the crowded corridor asking for help in a more insistent tone. Somehow the other six of my fellow travellers had realised I was an English doctor, and now one of them dashed out, gesticulating furiously, and brought the guard to me. I was feeling extremely un-English and un-medical. My tweed jacket and corduroy trousers were not the most professional of garments, and I had just cut myself a large piece of Bologna sausage with my massive penknife. Driven more by the contemptuous glances of my companion than any love for my fellow men, I allowed myself to be led away, leaving my companion telling the others that I was not a fair sample of the English medical profession, who, as a whole, were a fine upstanding body of well dressed men and only too ready to help.

As I passed down the train, people standing in the corridor patted me on the back and hoped I would find the patient not too bad. Arriving at the scene of the turmoil I found a young Italian woman stretched out on the seat, covered with coats and blankets, shivering violently. She had a baby of six months with her and a little girl who was staring out of the window. The baby was being looked after by an admirable body from Manchester, whose husband was doing his best to keep the compartment in order and prevent innumerable curious Italian males from coming in to look at the attractive victim. The guard announced that he had brought a doctor, the woman moaned, opened her eyes to look at me, and gave a tremendous howl. It was then that I realised I was bending over her with my penknife still open.

My questioning of the patient was not at all successful, so the lady from Manchester told me that the woman had joined the train at the Italo Swiss frontier some 15

hours earlier and had been vomiting or retching for the past 12. I immediately thought of some abdominal crisis and tried to examine the appropriate part, but this led to more howls and protestations, in which the baby joined. I realised we were getting nowhere fast, so I sat down and attended to the baby, on the principle that it's easier to think in peace than in a noise. The Englishman produced his hip flask and I still had some barbiturate from the previous night, so I made a brew and gave the baby a few sips of it when the train conveniently stopped before crossing a newly repaired bridge. The concoction worked admirably. I then went all the way back for my companion—past all the back-slapping well-wishers who were now keen to know the diagnosis—and persuaded her to act as interpreter. This proved unexpectedly difficult because the woman spoke a peculiar dialect and was having a violent rigor. I decided it was imperative to palpate her abdomen, and eventually managed to get my left hand somewhere under her left costal margin. *S.A.D.* Further questions. Had she had any food today? No. Had she ever had a similar attack? Yes, the only time she had been on a train journey before. Train-sickness, that was it. I gave her the remainder of the baby's mixture. Soon she was fast asleep, and the train obligingly moved forward.

The daughter, aged about 7, now took an interest in the proceedings, and asked in very matter-of-fact tones, "Will she wake up in time to get out at Rome?" The question seemed to indicate a practical mind, so we began to question her. Her name was Maria and they were going to Rome to stay with her uncle, whom she had met once and was sure she would recognise again. At last we reached Rome, where my companion and Maria went off to look for Uncle, and also for my companion's friend whom she had not seen for some years. Neither was there. We stayed on the train until the cleaners turned us out, and then a rather bedraggled group set off to find accommodation for the night.

Just as we left the station, the friend arrived. His face, when he saw my companion holding a baby, accompanied by a rough-looking stranger leading a small girl and supporting a semicomatose Italian, made up for everything.

* * *

Just before I left America, I optimistically sent off one of those postcards that one gets saving. "Dear Dr. Pedantic, I should appreciate a copy of your article, *Melons as a cure for gout*, which appeared in *J. contemp. Idiocrac* for June, p 12345." Optimistically because it was to China, and those of us who have never been further East than Marseilles often look on China as backward in modern times, though of course we know all about the Chinese having aeroplanes (or was it wireless?) in 2000 B.C. So judge my surprise when I received an envelope covered with the most fascinating ideographs and containing not a reprint but a microfilm strip of the article. Now I am looking for a "reader." Perhaps if someone in China sees this?

kinds were thrown together into a single system by the National Health Service Act for reasons almost wholly unconnected with the principles of their internal management. The old dual system of hospitals was abandoned because of the lack of planning of the service as a whole, poor distribution of consultants, and so on. Nobody ever argued that it would be a good thing to pool the two principles of administration and hope for the best, but that is what happened when the Act provided for setting up hospital management committees without prior consideration of how they were to be expected to exercise the functions we have been discussing. Since the Act was passed the tendency of the Ministry of Health has been, on the whole, towards the central or voluntary pattern described above, stressing in particular consultant staffing with lay administration, though the principles lying behind these arrangements have often not been understood.

The departures from the older central pattern discernible in the present conception of the "hospital management committee" are indeed worth drawing out in order

1 The distinction between the administrative responsibility of the committee and the advisory status of the medical staff has been blurred by the appointment of members of the medical staff of the hospitals concerned to the hospital management committee otherwise than on the nomination of the medical committee.

2 The medical staff of the hospital management committee, though they are its own "better half," owe less than complete allegiance to it, since they are appointed and paid by the regional hospital board. Moreover, the medical staff has become too numerous to act as a medical staff committee in direct relationship with the hospital management committee, and a small medical advisory committee has been called into being to discharge this function.

3 The primary administrative function—the enlightened pursuit of economy—has been blunted in three ways. First, by the failure to give the committee full financial responsibility within its total allocation. Though it prepares its own estimates and thereby possesses a great power to influence the direction of expenditure, it is denied the power to "save" for its own purposes. Secondly, the chief administrative officer, though automatically responsible for economy by reason of the nature of hospital administration, is required to share his responsibility with his finance officer, whose very title is an importation from the other tradition where finance is regarded as a separate function. Thirdly, a new doctrine has been loosely imported, probably from industry, that it is the function of members of the hospital management committee to represent—even to protect—the consumer. Sometimes indeed they seem to be appointed to protect the interests of particular categories of hospital worker. This is very far from the true tradition, which regards their function as the wise spending of the limited resources at their disposal in accordance with the guidance of the medical and nursing staff.

4 The old pattern whereby the administrative authority of the hospital was vested in a relatively small and compact house committee and in the chairman and chief administrative officer, finds only a feeble counterpart in a hospital management committee. Responsibility tends to be regarded as vesting solely in the committee, which itself meets monthly, and the principal officers—the chairman and the secretary—are often reluctant to claim authority to act. Their authority to take action is rarely specified in standing orders.

5 The full professional responsibility entrusted to the matron by the Florence Nightingale tradition is inevitably distributed among the various matrons in the

different hospitals, whether or not arrangements are made for a "group matron" with some supervisory responsibility. This may be no disadvantage, having regard to the growth in size of the nursing responsibilities, but again it tends to disrupt the old tripartite arrangement. Often no matron is present at the meetings of the hospital management committee.

Some Principles

From such a background as this, is it possible to draw out any principles for guidance in the future, or must we settle down simply to make the best of the muddle that results?

Well, let us try, partly by way of elucidation and partly recapitulation.

The *first principle* is that the administration not only entrusts the medical care of the patients to the medical staff, but also looks to the medical staff for advice in regard to the management of the hospital. And from this there follows the corollary that in matters that affect the administration of the hospital, as distinct from the medical care of the individual patients admitted to their care, the medical staff must invariably act through the medical committee (or "medical advisory committee") and refrain from exerting pressure on the administration save through the recognised channel.

(We may remark in parentheses that these objectives are best furthered if medical men sit on the governing body as chosen representatives of the medical committee, and not otherwise.)

The *second principle* is that the administration entrusts the nursing care of the patients and the control of the nursing staff to the matron, and in dealing with questions that may affect the nursing of the patients, looks to its matron for advice. The committee must recognise her professional responsibility for her arrangements—except indeed in so far as she may be acting, as she often does for convenience, as an administrative officer of the hospital.

(We may remark in parentheses that if a "nursing committee" is set up alongside the matron its scope and functions need to be clearly defined, for there are certain matters which cannot be thus delegated without destroying the matron's proper professional responsibility. It should probably be regarded as advisory to the matron, not as a subcommittee of the board carrying executive powers. If it is argued that the calibre of those seeking the position is too often unequal to the responsibility, it may fairly be asked if women of ability will be attracted to matrons' posts unless they offer ample scope of a true professional kind.)

The *third principle* is that the administrative authority, being concerned with the enlightened pursuit of economy, endeavours so to dispose of the resources of the hospital as best to meet the needs of the patients and with due regard to the advice of the medical and nursing staff. And from this it follows as a corollary that the administrative authority should be composed of men and women of the right sort, chosen for their experience of affairs, including financial affairs, and proved ability to choose staff of the right kind, and not because they "represent" particular aspects of "consumer interest."

(Again we may remark in parentheses that if the local administration is deprived of the power to dispose of the resources of the institution as it deems best in accordance with the advice of its medical and nursing staff, it might as well be dissolved forthwith and the hospital handed over to the Assistance Publique de Paris.)

"If we were perfect, no doubt an absolute hierarchy would be the best kind of government for all institutions. But in our imperfect state of conscience and enlightenment, publicity and the collusion resulting from publicity, are the best guardians of the interests of the sick."

FLORENCE NIGHTINGALE, *Notes on Hospitals*

In England Now

A Running Commentary by Peripatetic Correspondents

My shaggy blue roan cocker bitch (who is not so damn' shaggy as all that) did not display her usual enthusiasm when invited to come and walk partridges with me on Saturday. "Of course, I'd love to come," she cooed in her mincing Cambridge accent, "but *actually* I've got the most fearful rheumatism in my off hind"—and she limped around on three legs wagging the rest of herself, a well known technique employed to excite sympathy. I examined the limb but was unable to elicit any abnormal physical signs. "You'd better come," I suggested, "you'll enjoy the ride and you needn't hunt if you don't want to." Protesting genteelly she allowed herself to be lumped into the car. Arrived at the farm where we shoot, I helped her out and started to walk across a rough field. Looking like a martyr, she limped dutifully behind. Presently we put up a rabbit. "Look, look!" she screamed and gave chase, as she always does, despite all my rating and whistling. As usual the rabbit made the hedge safe with a dozen yards to spare and she came bounding back. "What about that rheumatism?" I asked. She made no reply but proceeded to quarter the field on four legs as thoroughly as ever. We've heard no more about it. Functional, you see.

* * *

The Peripatetic Pathologist from Portsmouth, who ministered to the needs of the lady in the train soon after it left Grand Central Station, had a much easier time than I did on my way to Rome just after the war. The Paris-Milan-Rome express was not yet restored to its pre-war comfort and 'Mussolman efficiency' and I had spent the last few hours wondering how late we would arrive in Rome—would we be 16 or 20 hours behind schedule?

My companion, who believed in comfort at all times, was in a foul temper, and trying hard to get some much needed beauty-sleep when the guard came down the corridor, asking if there was a doctor on the train. Once before, in my early enthusiastic days, I had got into an unfortunate position by bounding forward when such a cry was raised, so I cringed back in the darkest corner of the compartment. When the guard had gone by, my companion rounded on me and scornfully demanded why I didn't help. I was trying to explain when the guard returned up the crowded corridor asking for help in a more insistent tone. Somehow the other six of my fellow travellers had realised I was an English doctor, and now one of them dashed out, gesticulating furiously, and brought the guard to me. I was feeling extremely un-English and un-medical. My tweed jacket and corduroy trousers were not the most professional of garments, and I had just cut myself a large piece of Bologna sausage with my massive penknife. Driven more by the contemptuous glances of my companion than any love for my fellow men, I allowed myself to be led away, leaving my companion telling the others that I was not a fair sample of the English medical profession, who, as a whole, were a fine upstanding body of well-dressed men and only too ready to help.

As I passed down the train, people standing in the corridor patted me on the back and hoped I would find the patient not too bad. Arriving at the scene of the turmoil I found a young Italian woman stretched out on the seat, covered with coats and blankets, shivering violently. She had a baby of six months with her and a little girl who was staring out of the window. The baby was being looked after by an admirable body from Manchester, whose husband was doing his best to keep the compartment in order and prevent innumerable curious Italian males from coming in to look at the attractive victim. The guard announced that he had brought a doctor, the woman moaned, opened her eyes to look at me, and gave a tremendous howl. It was then that I realised I was bending over her with my penknife still open.

My questioning of the patient was not at all successful, so the lady from Manchester told me that the woman had joined the train at the Italo Swiss frontier some 15

hours earlier and had been vomiting or retching for the past 12. I immediately thought of some abdominal crisis and tried to examine the appropriate part, but this led to more howls and protestations, in which the baby joined. I realised we were getting nowhere fast, so I sat down and attended to the baby, on the principle that it's easier to think in peace than in a noise. The Englishman produced his hip flask and I still had some barbiturate from the previous night, so I made a brew and gave the baby a few sips of it when the train conveniently stopped before crossing a newly repaired bridge. The concoction worked admirably. I then went all the way back for my companion—past all the back-slapping well-wishers who were now keen to know the diagnosis—and persuaded her to act as interpreter. This proved unexpectedly difficult because the woman spoke a peculiar dialect and was having a violent rigor. I decided it was imperative to palpate her abdomen, and eventually managed to get my left hand somewhere under her left costal margin. *N.A.D.* Further questions. Had she had any food today? No. Had she ever had a similar attack? Yes, the only time she had been on a train journey before. Trainsickness that was it. I gave her the remainder of the baby's mixture. Soon she was fast asleep, and the train obligingly moved forward.

The daughter, aged about 7, now took an interest in the proceedings, and asked in very matter-of-fact tones, "Will she wake up in time to get out at Rome?" The question seemed to indicate a practical mind, so we began to question her. Her name was Maria and they were going to Rome to stay with her uncle, whom she had met once and was sure she would recognise again. At last we reached Rome, where my companion and Maria went off to look for Uncle, and also for my companion's friend whom she had not seen for some years. Neither was there. We stayed on the train until the cleaners turned us out, and then a rather bedraggled group set off to find accommodation for the night.

Just as we left the station, the friend arrived. His face, when he saw my companion holding a baby accompanied by a rough-looking stranger leading a small girl and supporting a semicomatose Italian, made up for everything.

DISEASES OF THE CENTRAL ADAPTATION SYNDROME IN AFRICANS

SIR,—I have only lately been able to read the Heberden oration delivered by Professor Selye on June 21. Previously I had paid but little attention to his work because he appeared to be working with diseases uncommon among Africans in this part of the continent.

The almost complete absence of some diseases, such as disseminated sclerosis, in most of Africa, including South Africa, may reflect the absence of an infection, or the presence or absence of some trace element in the local soils and foodstuffs. But neither the absence of an infection, nor climatic factors, by themselves, will explain the fact that a great number of diseases common in Europeans and Asians are quite uncommon among the local inhabitants, although apparently present in almost their normal distribution among the descendants of the negro race in the warmer parts of the U.S.A. and Central America. Doubtless a genetic factor can be invoked in certain conditions, this may operate in the very low incidence of pernicious anaemia, of which I have seen only quite recently my first typical case in an African.

It would be wrong to suggest that diseases of stress do not occur among Africans in Uganda, but it is almost certainly true that many of these diseases are far less common among them than among Asians and Europeans living under similar climatic environment but having a different genetic background, a different incidence of tropical and other infections, and a different diet. The following diseases are far less common in Africans—rheumatoid arthritis, psoriasis, essential hypertension, coronary artery disease, hypertensive cerebral haemorrhage, thyrotoxicosis, and peptic ulcer. The following diseases are probably less common, though it is difficult to collect accurate data: atopic dermatitis and eczema, gout, hay-fever, and Hodgkin's disease. Upon many of the so-called diseases of stress it is difficult to offer any definite opinion. Rheumatic fever is uncommon, on the other hand, some would say that streptococcal sore throat is not so common in these parts, and true acute haemorrhagic nephritis (Ellis type 1) is very rare. Keloids, and hepatitis and cirrhosis of the liver—diseases which may, it is suggested, respond to adrenocorticotrophic hormone or 'Cortisone'—are extremely common.

Professor Selye seems to have grouped together under his title of "diseases of the general adaptation syndrome" the large majority, but not all, of the diseases which are uncommon among Africans. This is more than a coincidence: it is a fact of overwhelming importance. Probably, however, none of these diseases is totally absent, and my clinical impression is that they are commoner among upper class Africans, who are better fed and less exposed to certain infections. At present the African appears able to prevent these diseases to an extent which those who regard themselves as advanced can only envy.

May I, in conclusion, express my personal debt to Prof. Joseph Gullman, who introduced me to the relation between chronic malnutrition and the endocrine glands, the latter being often abnormal in Africans.

Thanks are due to the Director of Medical Services Uganda, for permission to publish this communication.

POSTURE

SIR,—Dr Lise Gellner (July 15) and Dr Mungo Douglas (July 29) raise important points in connection with the "primary control" described by F. M. Alexander and mentioned in my article on his work (July 1).

I think there is no reason now to doubt the prevalence of "head retraction" under civilised conditions, and undoubtedly this defect has an important influence on the "manner of use" of the rest of the body. There are at least three schools of thought on this question of what constitutes the primary defect in conditions of faulty body mechanics. One school blames the pelvis, another the head, and a third the foot, and accordingly one of these three is singled out as the primary subject for re-education.

Most orthopaedic and physical medicine authorities follow Wiles in stressing the importance of the pelvis.¹ Mr Alexander, Prof. Raymond Dart, and a few others stress the importance of the head-neck relationship. Both on theoretical and practical grounds, I am convinced that this last view is the right one. The head, after all, carries the balancing apparatus—the labyrinth—and in addition it carries the eyes, which have an important reflex influence on posture. Added to this, there are the attitudinal reflexes of Magnus, which are evoked from the cervical musculature. The pelvis carries no organs which have any particular relevance to the reflex control of posture.

Dr Gellner asks *why* the head should so often be retracted, and blames the heel on the infant's shoe for this defect, in fact, she makes the foot "primary" to the head. My own view is that the number of such harmful influences which may encourage head retraction, must be legion. I have in front of me a beautiful series of photographs which illustrate the harmful effect of encouraging infants to sit up too soon, before there has been adequate neuromuscular maturation. Likewise, one can blame faulty maternal handling, faulty school furniture, faulty shoes, unenlightened physical exercise programmes which encourage too rapid and too tense muscular responses—and so on.

In dealing with this question of what is the "primary" cause of faulty body mechanics, it is helpful to consult philosophers, and to find out exactly what is meant by "causation" and "explanation." Gilbert Ryle,² in a book which ought to be compulsory reading for writers on medical subjects, points out that there are at least two quite different senses in which an occurrence is said to be explained. There are accordingly at least two quite different senses in which we ask "why" it occurred and two quite different senses in which we say that it happened "because" so and so was the case. The first sense is the causal sense. Consider the simple example of a stone striking a piece of glass and breaking it. To ask why the glass broke is to ask what caused it to break, and we explain, in this sense, the breaking of the glass when we report that a stone hit it. But very frequently we look for and get explanations of occurrences in another sense of "explanation." We ask why the glass broke, and we get the answer that it was because the glass was brittle. "Brittle" is a dispositional adjective, that is to say, to describe the glass as brittle is to assert a general hypothetical proposition about the glass.

In answering this question of "why" the head is retracted, I prefer to stick to a "dispositional" account, rather than to look for extraneous "stones" like the heel on the infant's shoe. An anatomical account is a satisfactory approach, and the following account is taken from Professor Dart.³

¹ Wiles, P. *Essentials of Orthopaedics*. London, 1949.
² Ryle, G. *The Concept of Mind*. London, 1949.
³ Dart, Raymond. *S Afr med J* 1947 21 72.

The muscles which look after the relationship of the head with the vertebral column in man (and other primates) have cranial insertions mainly confined to the occipital bone but there is a great disparity in number, strength, and size between the anterior (or flexor) group of muscles and the posterior (or extensor) group. The force of gravity compensates for the relatively few weak and small flexors in pronograde animals, but in a creature such as man this disparity between strong head extensors and weak head flexors is accentuated by the orthograde posture.

The spinal accessory nerve supply of the trapezius further complicates this business of "head retraction," because of the entirely reflex or automatic functions in which it participates. The spinal half of the accessory nucleus is intimately concerned with all movements and postural adjustments of the head via the trapezius and sternomastoid, meanwhile the cranial portion of the nerve is inextricably associated with all of the movements of the pharynx in swallowing and of the larynx in respiration and vocalisation. Arising coterminously from the same four medulla oblongata neuromeres as give origin to the glossopharyngeal, vagus, and accessory nerves, the hypoglossal nucleus controls the movements of the tongue in mastication and swallowing. To carry out these almost automatic or reflex functions at the same time as the body is being held erect is a complex task, calling for a high degree of co-ordination, and for an adequate kinaesthetic appreciation of the head-neck relationship. The kinaesthetic appreciation of this region is almost always defective,⁴ but the defect can be put right by suitable re-education, with a resultant improvement in the management of the rest of the body.

In his achievement of the erect posture, man has had to over-emphasise the extensor mechanism at the expense of the flexor. "Conditions of civilisation"—I doubt if one can be more specific than this—make more difficult the maintenance of what is already a complex anatomical arrangement in the head-neck region. From a practical point of view, the focusing of re-educational work on the head-neck relationship as a "primary control" is most effective. I personally am convinced by practical experience that this "primary control" is a reality, and that its presence cannot be ignored when we are carrying out re-educational work.

London, S W 7

WILFRED BARLOW

MENINGITIS LEPTOSPIROSA

SIR,—The report of a further case of meningitis leptospiroza by Dr Geffen and Dr Tinker (Aug 5) is to be welcomed during the present epidemic season of poliomyelitis. A similar case has recently been seen at this hospital. Alston and Broom⁵ at this time last year drew attention to the difficulty of differentiating between leptospirosis and non-paralytic poliomyelitis.

On Aug 12, 1950, a boy, aged 7 years, was transferred to the tuberculous meningitis unit of this hospital from an isolation hospital in an area where poliomyelitis has recently occurred. He had a history of headache, vomiting, abdominal pain, and fever for three days. On admission to the isolation hospital (under the care of Dr A. D. C. Cameron) on Aug 9, he had neck stiffness but no other abnormal signs in the nervous system. Examination of the cerebrospinal fluid (c.s.f.) showed 4 cells per c.mm., protein 40 mg per 100 ml, chlorides 710 mg per 100 ml, and sugar normal. Three days later the fluid contained 252 cells per c.mm. (60% lymphocytes, 40% polymorphs), protein 40 mg per 100 ml, chlorides 710 mg per 100 ml, and sugar normal.

On admission to this hospital he had a temperature of 100°F and neck stiffness. He was fully conscious. No conjunctivitis, muscle tenderness, or paralysis was noted. On Aug 13 the c.s.f. contained 200 cells per c.mm. (90% lymphocytes), protein 30 mg per 100 ml, chlorides 700 mg per 100 ml, and sugar 98 mg per 100 ml. No tubercle bacilli were seen. The Mantoux reaction was negative (1 in 1000) and radiological examination of the chest revealed no abnormality. Two days later conjunctivitis was noticed in the morning but was absent in the afternoon.

On Aug 15 agglutinins were present in the serum against *Leptospira canicola* up to 1 in 300, and against *L. icterohaemorrhagiae*

up to 1 in 300 with a trace at 1 in 1000. On Aug 22 the titre for *L. canicola* had risen to 1 in 1000, and for *L. icterohaemorrhagiae* it was 1 in 300 (Archway group laboratory).

Conjunctivitis or suffusion of the eyes, which may be mild and transient, is an important clinical sign in leptospirosis. The level of urea in the blood is usually raised,⁶ and the c.s.f. glucose level is within normal limits. It is the practice in our tuberculous meningitis unit to carry out serological investigations for leptospirosis and infectious mononucleosis in all patients with lymphocytic non-tuberculous meningitis in whom an alternative aetiology is not readily apparent.

A diagnosis of infantile paralysis not unnaturally causes considerable anxiety at the present time, and it is therefore important to distinguish patients who have leptospirosis, because of the difference in prognosis.

Whittington Hospital London, N 19

W L CALNAN

MEIGS'S SYNDROME

SIR,—In your issue of Aug 5, Dr Beresford and Dr Aidin point out that cases of Meigs's syndrome are often admitted to a medical ward with a diagnosis of congestive heart failure or of cirrhosis of the liver, both of which can be associated with ascites and hydrothorax. This is undoubtedly so. It is possible that in some instances of cirrhosis of the liver (and perhaps of heart-failure, polyserositis, or multiple tuberculous effusions) the mechanism of production of hydrothorax associated with ascites is similar to that in Meigs's syndrome.

The following fatal case of cirrhosis of the liver illustrates this possibility.

A boy, aged 11 years, was admitted to the General Infirmary at Leeds on Sept 23 1949, with a history of malaise and cough starting three weeks previously. Slight jaundice was noticed twelve days after the onset. On admission there was gross ascites, oedema of the ankles, smooth enlargement of the liver to the umbilicus, a palpable spleen, and a massive right hydrothorax with no evidence of effusion on the left side. Serum proteins were 5.5 g per 100 ml, with albumin 2.2 g and globulin 3.3 g per 100 ml. His condition remained little altered and fluid re-accumulated in the right chest in spite of repeated aspiration, until Oct 10 when he developed severe right-sided abdominal pain and fever. This became worse after abdominal paracentesis, and it was thought that peritonitis had developed. There was little response to penicillin and sulphamezathine, and he gradually became confused and died in coma on Oct 19.

Post-mortem examination (Dr D. H. Collins) showed a coarse cirrhosis with postnecrotic scarring, and confirmed the presence of ascites and massive right hydrothorax. The left pleural sac showed no abnormality beyond interlobar adhesions. The pericardium contained a small amount of clear fluid. The omentum and the surface of the peritoneal cavity was congested, and similar changes were seen in the right pleura particularly over the diaphragm. The left pleural surface and diaphragm were normal apart from several small petechial haemorrhages. Histological examination of the omentum showed dilatation of capillaries and veins which were engorged with blood and a light infiltration of lymphocytes with a much smaller number of neutrophils and eosinophils. The right diaphragm showed similar changes on its peritoneal surface, but the inflammatory reaction was much more intense on the pleural surface and there were small pockets of pus cells.

Though the serum proteins were much reduced, and this reduction might account for the ascites and oedema of the ankles, it is difficult to explain the massive right hydrothorax on this basis alone, particularly in the absence of any fluid in the left pleura. It seems possible that its mechanism of production might be similar to that of the pleural effusion (commonly on the right) which occurs in Meigs's syndrome. The distribution of the changes in the acute inflammatory episode affecting the peritoneum and the right diaphragm and pleura

POSTURE

DISEASES OF THE CENTRAL ADAPTATION SYNDROME IN AFRICANS

SIR,—I have only lately been able to read the Heberden oration delivered by Professor Selye on June 2¹. Previously I had paid but little attention to his work because he appeared to be working with diseases uncommon among Africans in this part of the continent.

The almost complete absence of some diseases, such as disseminated sclerosis, in most of Africa, including South Africa, may reflect the absence of an infection, or the presence or absence of some trace element in the local soils and foodstuffs. But neither the absence of an infection, nor climatic factors, by themselves, will explain the fact that a great number of diseases common in Europeans and Asians are quite uncommon among the local inhabitants, although apparently present in almost their normal distribution among the descendants of the negro race in the warmer parts of the U.S.A. and Central America. Doubtless a genetic factor can be invoked in certain conditions, this may operate in the very low incidence of pernicious anaemia, of which I have seen only quite recently my first typical case in an African.

It would be wrong to suggest that diseases of stress do not occur among Africans in Uganda, but it is almost certainly true that many of these diseases are far less common among them than among Asians and Europeans living under similar climatic environment but having a different genetic background, a different incidence of tropical and other infections, and a different diet. The following diseases are far less common in Africans: rheumatoid arthritis, psoriasis, essential hypertension, coronary-artery disease, hypertensive cerebral haemorrhage, thyrotoxicosis, and peptic ulcer. The following diseases are probably less common, though it is difficult to collect accurate data: atopic dermatitis and eczema, gout, hay-fever, and Hodgkin's disease. Upon many of the so-called diseases of stress it is difficult to offer any definite opinion. Rheumatic fever is uncommon, on the other hand, some would say that streptococcal sore throat is not so common in these parts, and true acute haemorrhagic nephritis (Ellis type-1) is very rare. Keloids, and hepatitis and cirrhosis of the liver—diseases which may, it is suggested, respond to adrenocorticotrophic hormone or 'Cortisone'—are extremely common.

Professor Selye seems to have grouped together under his title of "diseases of the general adaptation syndrome" the large majority, but not all, of the diseases which are uncommon among Africans. This is more than a coincidence: it is a fact of overwhelming importance. Probably, however, none of these diseases is totally absent, and my clinical impression is that they are commoner among upper class Africans, who are better fed and less exposed to certain infections. At present the African appears able to prevent these diseases to an extent which those who regard themselves as advanced can only envy.

May I, in conclusion, express my personal debt to Prof. Joseph Gullman, who introduced me to the relation between chronic malnutrition and the endocrine glands, the latter being often abnormal in Africans.

Thanks are due to the Director of Medical Services Uganda, for permission to publish this communication.

SIR,—Dr Lise Gellner (July 15) and Dr Mungo Douglas (July 29) raise important points in connection with the "primary control" described by F. M. Alexander and mentioned in my article on his work (July 1).

I think there is no reason now to doubt the prevalence of "head retraction" under civilised conditions, and undoubtedly this defect has an important influence on the "manner of use" of the rest of the body. There are at least three schools of thought on this question of what constitutes the primary defect in conditions of faulty body mechanics. One school blames the pelvis, another the head, and a third the foot, and accordingly one of these three is singled out as the primary subject for re-education.

Most orthopaedic and physical medicine authorities follow Wiles in stressing the importance of the pelvis.¹ Mr Alexander, Prof. Raymond Dart, and a few others stress the importance of the head-neck relationship. Both on theoretical and practical grounds, I am convinced that this last view is the right one. The head, after all, carries the balancing apparatus—the labyrinth—and in addition it carries the eyes, which have an important reflex influence on posture. Added to this, there are the attitudinal reflexes of Magnus, which are evoked from the cervical musculature. The pelvis carries no organs which have any particular relevance to the reflex control of posture.

Dr Gellner asks why the head should so often be retracted, and blames the heel on the infant's shoe for this defect, in fact, she makes the foot "primary" to the head. My own view is that the number of such harmful influences which may encourage head retraction, must be legion. I have in front of me a beautiful series of photographs which illustrate the harmful effect of encouraging infants to sit up too soon, before there has been adequate neuromuscular maturation. Likewise, one can blame faulty maternal handling, faulty school furniture, faulty shoes, unenlightened physical exercise programmes which encourage too rapid and too tense muscular responses—and so on.

In dealing with this question of what is the "primary" cause of faulty body mechanics, it is helpful to consult philosophers, and to find out exactly what is meant by "causation" and "explanation". Gilbert Ryle,² in a book which ought to be compulsory reading for writers on medical subjects, points out that there are at least two quite different senses in which an occurrence is said to be explained. There are accordingly at least two quite different senses in which we ask "why" it occurred and two quite different senses in which we say that it happened "because" so and so was the case. The first sense is the causal sense. Consider the simple example of a stone striking a piece of glass and breaking it. To ask why the glass broke is to ask what caused it to break, and we explain, in this sense, the breaking of the glass when we report that a stone hit it. But very frequently we look for and get explanations of occurrences in another sense of "explanation". We ask why the glass broke, and we get the answer that it was because the glass was brittle. "Brittle" is a dispositional adjective, that is to say, to describe the glass as brittle is to assert a general hypothetical proposition about the glass.

In answering this question of "why" the head is retracted, I prefer to stick to a "dispositional" account, rather than to look for extraneous "stones" like the heel on the infant's shoe. An anatomical account is a satisfactory approach and the following account is taken from Professor Dart.³

¹ Wiles P. *Essentials of Orthopaedics*. London 1949.
² Ryle G. *The Concept of Mind*. London 1949.
³ Dart Raymond. *S Afr med J* 1947 21 74.

sponding with date of onset, (2) typical allergic picture, (3) definite leucocytosis, (4) painlessly enlarged liver, (5) positive patch tests, and (6) the recent description of similar cases occurring during P.A.S. therapy, it seems that this is a case of toxic hepatitis due to P.A.S.

EVELYN HESS
D G ISMAT

Tuberculosis Unit
West Middlesex Hospital,
Isleworth.

SIR,—The following case is essentially similar to those described by Dr Cuthbert and correspondents who have written since his letter appeared

The patient was a youth, aged 19, with fairly long standing productive tuberculosis in the left upper lobe. The lesion was cavitated, and there was evidence of localised endobronchitis with slight recent deterioration. He had been afebrile for some months and was in good general condition.

On July 15 1950, streptomycin 1 g daily and P.A.S. 15 g daily was begun. There was no diarrhoea vomiting or anorexia but on the 20th day of treatment the patient complained of lassitude and was found to have a temperature of 100 F. The next day he became more ill and towards the evening complained of frontal headache, shivering, and a 'hot' skin. The temperature rose to 103.5 F and the pulse rate to 120 per min., but there were no other physical signs. On the 23rd day the temperature rose to 104.5 F, and simultaneously the patient developed a generalised papulo-erythematous rash, which began on the backs of the hands and spread from the extremities to the trunk and face. The palms and soles escaped, and itching was confined to the latter. He also complained of a severe sore throat with difficulty in swallowing; the throat was very red and slightly oedematous. The tongue was heavily coated. His face was flushed and looked puffy, and there was well marked injection of the conjunctivae. No enlarged glands were felt.

The next day he appeared extremely ill, with malaise and prostration, in the evening the temperature again reached 104.5 F and the rash had become more noticeable. Up to this time blood-counts had shown 8-12% monocytes but were otherwise normal. Throat swabs had shown no pathogens and three specimens of urine had shown no albumin, cells or casts. No icterus developed.

On the 25th day P.A.S. and streptomycin were discontinued. The temperature promptly fell to normal and the rash faded within 48 hours without subsequent desquamation. Patch tests on Aug 12 with 20% P.A.S., 20% sodium salicylate, and 20% streptomycin were all negative. There were no further developments and the patient seemed quite well. The Paul Bunnell reaction was negative.

On Aug 21, 0.5 g P.A.S. was given. Within 3 hours the patient complained of generalised itching and shortly afterwards of sore throat, and the rash began to recur. There was no fever, headache or malaise. The symptoms subsided within 9 hours.

Desensitisation to P.A.S. was begun on Aug 23 with a daily dose of 100 mg which has been gradually increased. This has so far been carried out uneventfully. No anti-histamine drugs have been used.

Twenty six other patients have been treated with similar doses of the same preparation of P.A.S., and other than diarrhoea and anorexia in three cases there have been no toxic reactions.

PROPHYLACTIC INOCULATION AND POLIOMYELITIS

SIR,—The present anxiety in regard to a possible connection between inoculation against diphtheria and the occurrence of poliomyelitis raises many questions. One of these concerns the method of inoculation.

Practically all authorities have advocated the intramuscular route. Many years ago, when we were working with the original A.P.T. preparations of the Wellcome Laboratories, we encountered sterile abscesses from time to time. These still occur, though in an insignificant proportion of cases. It has always seemed to me that while the occurrence of such abscesses remained a possibility,

it was better that they should be superficial than deep and, accordingly, we have invariably administered these antigens by the subcutaneous route.

As I understand it, the present view appears to be that the injection of a foreign material into the substance of a muscle may have an irritant effect on nerve-endings and predispose them to the lodgement of poliomyelitis virus. This is, of course, hypothesis only, but it may be worth investigating. The main difficulty in this will, I think, be that in practically all cases previously inoculated the injection will have been made by the intramuscular route.

We have been fortunate in escaping poliomyelitis in this area. In the past three years only five cases have come to our notice, and in only one of these was there a history of immunisation. The child concerned had received a single injection of P.T.A.P. five months before the onset of the disease, and in his case the right leg was affected, the arms having completely escaped.

SALICYLATES IN ACUTE OSTEOMYELITIS

SIR,—In connection with the article of July 29 by Mr Konstam and Dr Meynell, we should like to refer to some of our findings.¹

We have shown in animals and in man that the effect of large doses of salicylate differs essentially from the effect of smaller doses. With large doses the body's non-specific defence mechanism is remarkably stimulated. For this reaction adrenal activity is indispensable, both adrenaline and the cortical hormones seem to take part in it. Sodium gentisate is less effective than sodium salicylate in evoking the reaction.

Our results shed new light on Coburn's² observations on the therapeutic significance of heavy doses of salicylate, and they again underline the importance of what has been termed the "alarm reaction"³—namely, the non-specific reaction mediated by the A.C.T.H. glucocorticoid mechanism. The therapeutic significance of these substances is well known.⁴

In some of our animal experiments salicylate was more effective than 4 mg A.C.T.H. or Cortisone⁵ per 100 g body-weight. Perhaps salicylate causes the release from the adrenal cortex of a different hormone. The beneficial effect of large doses of salicylate in several diseases—which so far has not been explained satisfactorily—may be also accounted for in this way.

IAN MACPHERSON

A LARGE BENIGN GASTRIC ULCER

SIR,—Though large gastric ulcers are often seen in every general hospital, the case described here is notable for the absence of any clinical indication of the site or the size of the ulcer and for the associated arterial calcification, the significance of which was not realised.

A railway fireman, aged 63, had had vague lower abdominal pain for more than six months. His appetite was very poor, and he had lost 2 st in weight. The pain was of an aching character and came on in attacks with seldom more than a week between them. The patient was extremely constipated and required increasingly large doses of aperients. He had passed blood per rectum on several occasions. He had had dysentery some years previously, had been stabbed in the abdomen in 1902, and had had his appendix removed in 1905.

On examination his abdomen was slightly distended and there was some visible peristalsis. No mass was palpable, and there were no other significant findings. After repeated washouts a barium enema gave a normal result, but considerable calcification in the abdominal aorta and other vessels was found. A barium meal revealed a huge ulcer occupying almost the whole of the lesser curvature (see figure). The ulcer was so large that its true nature was only shown by a bubble of air which was retained at the apex when the patient was standing. In the prone position it was more clearly outlined and the stomach was seen to be relatively immobile. There was very little opposing spasm and no peristalsis, and the pyloric antrum was narrowed, also showing poor peristalsis. Radiologically it was felt that the ulcer was probably malignant, and that the pylorus was probably also involved. A fractional test-meal was completely normal, and gastroscopy showed that the ulcer had a smooth grey floor with a nodular margin. The mucosa in the pyloric antrum appeared normal, but the ulcer as seen gastroscopically was thought to be malignant.

Radiogram after barium meal with patient erect showing large ulcer (between arrows) on lesser curvature

Operation—The abdomen was opened through a right paramedian incision, and the ulcer was found to be adherent to the pancreas. An almost total gastrectomy was performed, and a posterior anastomosis with a valve completed the operation.

Postoperative Progress—Apart from slight pyrexia on the twelfth day, recovery was normal. Four months later the patient had gained 2½ st in weight.

Pathology—The ulcer was more than 6 cm in diameter and had perforated all coats of the stomach. There was at least one artery in the necrotic base. There was no evidence of malignancy.

The discovery of the ulcer was a complete surprise, for there was no indication in the history or clinical examination that the stomach was the cause of the pain, much of which must have been referred from the pancreas. According to Elkeles,¹ a diagnosis of simple rather than malignant ulceration is supported by the well marked arterial calcification, although not all surgeons with experience of gastric surgery would subscribe to this view.

However, as this case demonstrates, the presence of advanced calcification in the gastric vessels is clearly an indication for laparotomy—even though the size and history of the ulcer, and other findings, are in favour of malignancy. nor does this calcification necessarily increase the risk of the operative removal of such an ulcer, provided the patient's general condition offers no contra indication.

Our thanks are due to Dr C T Andrews for the gastroscopy report, and Dr René Salm for the histological findings.

ACQUIRED SENSITIVITY TO SODIUM P.A.S

SIR,—The jaundice during P.A.S treatment described by Dr Cuthbert on Aug 5 and by correspondents since then prompts us to report a further case.

The patient is a married woman, aged 33, with acute exudative tuberculous infiltration of the right upper lobe. On admission to hospital on July 19, 1950, she was pyrexial, and on July 24 a course of streptomycin (1 g daily) and P.A.S (3 g four times daily) was commenced. The patient tolerated the drugs well and became afebrile.

On Aug 19 a fine erythematous eruption appeared on the legs. Both drugs were immediately stopped, but the rash became generalised, intensely irritating, and maculopapular in character. There was conjunctivitis and rhinitis, and the temperature rose to 100°F. 'Thephorn' was now administered, but the temperature rose further to 103°F, and at this stage the patient felt very ill with nausea and anorexia. The white cell count was 19,000 per cmm with 86% polymorphs, 13% lymphocytes, and no eosinophils.

By Aug 25 the temperature had settled, and the rash had lessened and was beginning to desquamate. On Sept 1, when only desquamation remained and thephorn had been discontinued, an icteric tinge was observed in conjunctivae and skin, the patient continued to feel well. By Sept 5 she was deeply jaundiced, the stools were clay coloured, and the urine was dark and contained bile pigments, the liver was easily palpable but not tender. The patient had no gastric symptoms and still had a good appetite. The white-cell count had fallen to 7000 per cmm (polymorphs 49%, lymphocytes 37%, and for the first time an eosinophilia of 11%). The blood urea was 28 mg per 100 ml, and all the empirical liver function tests were indicative of toxic hepatitis. The jaundice has persisted and the liver remains enlarged.

Before the onset of jaundice a series of patch tests were carried out with P.A.S, methaminophenol, streptomycin, and salicylic acid. There was a positive reaction to P.A.S and methaminophenol.

The diagnoses of acute infective hepatitis and homologous serum jaundice were considered, but in view of (1) absence of history of contact or venipuncture corre-

ACQUIRED SENSITIVITY TO SODIUM P.A.S

SIR,—The jaundice during P.A.S treatment described by Dr Cuthbert on Aug 5 and by correspondents since then prompts us to report a further case.

The patient is a married woman, aged 33, with acute exudative tuberculous infiltration of the right upper lobe. On admission to hospital on July 19, 1950, she was pyrexial, and on July 24 a course of streptomycin (1 g daily) and P.A.S (3 g four times daily) was commenced. The patient tolerated the drugs well and became afebrile.

On Aug 19 a fine erythematous eruption appeared on the legs. Both drugs were immediately stopped, but the rash became generalised, intensely irritating, and maculopapular in character. There was conjunctivitis and rhinitis, and the temperature rose to 100°F. Theophorin was now administered, but the temperature rose further to 103°F, and at this stage the patient felt very ill with nausea and anorexia. The white cell count was 19,000 per c.mm with 86% polymorphs, 13% lymphocytes, and no eosinophils.

By Aug 25 the temperature had settled, and the rash had lessened and was beginning to desquamate. On Sept 1, when only desquamation remained and theophorin had been discontinued, an icteric tinge was observed in conjunctivae and skin, the patient continued to feel well. By Sept 5 she was deeply jaundiced, the stools were clay coloured, and the urine was dark and contained bile pigments, the liver was easily palpable but not tender. The patient had no gastric symptoms and still had a good appetite. The white cell count had fallen to 7000 per c.mm (polymorphs 49%, lymphocytes 37%, and for the first time an eosinophilia of 11%). The blood urea was 28 mg per 100 ml, and all the empirical liver function tests were indicative of toxic hepatitis. The jaundice has persisted and the liver remains enlarged.

Before the onset of jaundice a series of patch tests were carried out with P.A.S, methaminophenol, streptomycin, and salicylic acid. There was a positive reaction to P.A.S and methaminophenol.

The diagnoses of acute infective hepatitis and homologous serum jaundice were considered, but in view of (1) absence of history of contact or venipuncture corre-

not seem to give much weight to this objection, since she uses the cases as arguments against the traction theory. She concludes that this theory cannot be maintained pointing out, however, that at present there is "no alternative theory to offer," it appears probable that the Arnold Chiari malformation takes place at an early stage of embryonic development, perhaps at the stage of closure of the medullary canal, as suggested by Schwalbe Gredig."

In 1941² and 1946⁴ I described two fetal cases of spina bifida with hydrocephalus internus and the Arnold Chiari malformation.

CASE 1—A foetus of 63 mm. Spina bifida partum aperta et partum subcutanea, diastatomyelia thoracica et lumbosacralis, myelocele thoracolumbalis. The tip of the conus medullaris behind the body of the 3rd sacral vertebra—i.e. at a level normal for the fetal stage, the medullary 2nd cervical segment on a normal level behind dens epistrophei. Hydrocephalus internus. Stenosis of the mesencephalic aqueduct. Malformation of the rhombencephalon with plunging and deformity of the vermis cerebelli (evidently an Arnold malformation at an early stage of development).

CASE 2—A foetus of 115 mm. Spina bifida subcutanea, myelocystocele in the lower part of the back. Accurate calculation of the vertebrae not possible owing to pronounced segmental anomalies. Obviously, however, the ascensus medullae spinalis had been obstructed since the tip of the conus medullaris was on a level with the 3rd vertebra from the caudal end of the spinal column. The medullary 2nd cervical segment on a normal level behind dens epistrophei. Hydrocephalus internus. Deformity of the rhombencephalon with plunging of the cerebellum in much the same way as in case 1.

In each of these two cases we evidently have the initial stage of an Arnold malformation. In one case the ascensus medullae spinalis had not yet asserted itself, and in the other it had not yet appeared in the upper cervical region. Thus, as I pointed out in 1946,⁴ van Houweninge Graafdyk's traction theory cannot be applied to these two cases. I concluded that the primary cause of the malformation is unknown but is the same factor that causes spina bifida. It is possible that in both my cases an interaction arose at an early fetal stage between hydrocephalus internus and the cerebellum rapidly growing in the posterior fossa. But it is impossible to say which was the earlier abnormality—the hydrocephalus or the cerebellar malformation. It may be supposed that in case 1 the stenosis of the aqueduct first caused the hydrocephalus, but this is, of course, by no means certain.

It should perhaps be emphasised that in these two cases we are dealing with an Arnold but not with a Chiari deformity. Really there is no reason to assume that these two components of the Arnold Chiari malformation must have a common origin. In these two cases, further development traction by the spinal cord (as suggested by van Houweninge Graafdyk) might perhaps finally have completed the picture by giving rise to a Chiari malformation.

One cannot always dismiss van Houweninge Graafdyk's traction theory merely because it cannot be applied to some cases. In case 1 the aqueduct stenosis may have been the first visible cause of the deformity of the rest of the hind-brain. The origin of a deformity which eventually seems homogeneous may, I believe, vary from case to case within certain limits. One must also take care not to consider the morphogenesis of these malformations simply from a mechanical point of view. The normally growing organism tends, irrespective of accidental external influences, to attain a certain functional form (the "Gestaltungsfunktion" of Roux 1895). This function may be disturbed in case of malformation so that the initially abnormal organism has a propensity towards an anomalous form. This form it endeavours to attain by all available means.

EDUCATION FOR GENERAL PRACTICE

SIR,—May I supplement Dr Naish's excellent letter last week from the point of view of coöperation between the local authority and the general practitioner?

Her statement "I have proved that local authorities can take children away from the G.P. only if he is willing" may, I think, be a little misleading. The local authority in York have done everything in their power to assist Dr Naish in establishing her own infant welfare clinic. One of our health visitors attends her clinics and plays the same rôle as a health visitor in a local authority clinic, seeing a large proportion of the patients, weighing babies, and giving advice where necessary. Our aim in this city is to interest general practitioners in preventive medicine and to assist them where possible to undertake this work for their own patients. It is only fair, therefore, to point out that the infant welfare clinic cited by Dr Naish is a joint local authority and general practitioner clinic.

ENURESIS AND HYPERSOMNIA

SIR,—I was very interested in Dr Meyer's letter of Sept 16 and the description of his two cases. I must point out, however, that my article (July 22) dealt with *adults only*, hence Dr Meyer's remarks are not relevant to my observations.

There is today much disagreement among child psychiatrists, paediatricians, and urologists on the aetiology of enuresis in childhood. Thus to be dogmatic on this subject is to ask for trouble. This was one of the reasons why I did not consider enuretic children in my series of cases. Dr Meyer quotes only two cases, but I would refer him to the letter from Dr Lewsen, in your issue of Aug 12 where there would appear to be evidence that my theory could apply to children as well. I have made no claim that it does. Child psychiatrists will agree, I am sure, that a large number of enuretic children do not respond to psychological treatment in spite of ingenious (and often specious) arguments that are put forward to support a psychogenic basis in the various cases. The difficulty is that these theories cannot be proved or disproved and therefore involve a large element of faith.

Finally, it was certainly not my intention to convey that enuresis in adults is secondary to deep sleep. I was at pains to show that the two symptoms were part of a syndrome which is central in origin.

R. STRÖM-OLSEN

THE PSYCHIATRIC SOCIAL WORKER

SIR,—I should like to endorse Dr Creak's statement last week that the contribution made by psychiatric social workers to mental health is invaluable.

Yet another aspect of their plight has not so far become generally known. I refer to the recent ruling of the Ministry of Health on the classification of these workers for superannuation purposes.

Before the appointed day psychiatric social workers in mental hospitals were classified as class 1 asylum officers with a retiring age of 55 and a contribution to the superannuation fund of 3% of their salaries. After the health service started they were given the option of remaining in the old asylum officers' scheme or joining the National Health Service superannuation scheme, to which they would contribute 6% of their salaries.

No indication was given that the pension would be less, and nothing was said to suggest that the retiring age was to be raised. In the event it appears that this is the case. The Ministry of Health has refused to classify psychiatric social workers as mental health officers, which means that many in mental hospitals who decided

ACTH IN PURPURA ANNULARIS TELANGIECTODES

SIR,—I have studied the effect of adrenocorticotrophic hormone (ACTH) in a case of purpura annularis telangiectodes (Majocchi's disease)

The patient had numerous typical lesions, the nature of which was proved histologically, on the lower extremities, and in the suprapubic and gluteal regions. The lesions started to regress from the 4th or 5th day of treatment, with profound improvement after 12 days. The total quantity of ACTH* administered in this period was approximately 50 mg.

SPINA BIFIDA, INTERNAL HYDROCEPHALUS, AND THE ARNOLD-CHIARI MALFORMATION

SIR,—Prof Dorothy Russell has recently given a comprehensive account of the pathology of internal hydrocephalus—an account distinguished by profound personal experience, wide reading, and accurate post-mortem analysis.

Professor Russell devotes one of her chapters to the connection between spina bifida, internal hydrocephalus, and the Arnold Chiari malformation. A few years ago I published some investigations on this subject, which do not seem to have come to Professor Russell's notice (This is quite natural since at that time the war interfered with communications). I should therefore like to comment on Professor Russell's work.

Professor Russell gives the following classification of spina bifida: (1) meningocele, (2) meningocele, and (3) spina bifida occulta. In 1925 Holmdahl gave the generally accepted definition of spina bifida as a malformation originating from disturbances of three roughly simultaneous, yet fundamentally different, processes of development, which are all essential to the normal evolution of the spinal cord from its open to its closed state. These processes are: (1) the final closing of the neural tube in the caudal neuropore, (2) the plunging of the embryonic spinal cord into the mass of undifferentiated cells forming the trunk-tailbud, (3) the final detachment of the superficial epithelium from the embryonic spinal cord and from these undifferentiated cells. From Holmdahl's and from my own investigations, I have found the best classification of spina bifida to be: (1) spina bifida aperta, where the embryonic neural tube remains open, (2) spina bifida subcutanea, where the embryonic neural tube has developed into one (or more) tubes. The first class comprises rachischisis and myelocele or meningocele, and the second class all other forms of spina bifida. Whether the deformity is cystic or not is of secondary importance in this connection.

Professor Russell's classification is not adequate. Meningocele is a disputed form of spina bifida. Even Denucé (1907) maintained that "la méningocele pure n'existe pas," and, as far as I know, there has never been described an unequivocal case of pure meningocele—i.e., cystic hernia like bulging of the spinal meninges without spinal cord deformity. It is, in fact, difficult to find a place for such a deformity in Holmdahl's outline of the morphogenesis of spina bifida malformations. It is true that a bulging of the meninges—a meningocele—may be supposed to arise as a later complication of spina bifida, but this is another matter. None of the cases in Professor Russell's record fulfils the criteria of a pure meningocele.

The conception of spina bifida occulta is also vague. Some cases really deserve this name—i.e., cases of a

non cystic subcutaneous spina bifida—but these are comparatively rare. The term has also, and incorrectly, been applied where a simple dehiscence of one or more vertebral laminae has been misinterpreted as a pathological phenomenon. These cases have nothing to do with real spina bifida but are normal variants. Throughout infancy—and indeed later—unclosed laminae in the lumbosacral region are the rule rather than the exception (Hintze 1922, and others). Professor Russell's case 22 seems to be a misinterpreted normal case, so far as the lumbosacral area is concerned, with dehiscence in the sacral laminae inside a foveola coccygia.

Professor Russell's classification does not allow for von Recklinghausen's myelocystocele—a form of spina bifida whose existence was doubted (Leveuf Foulon 1930, Leveuf 1936) but has been proved.

With most spina bifida the embryonic spinal cord does not become detached from the superficial cover at the site of the deformity. To the cranial side of the malformation the ascensus medullae spinalis is obstructed during the continued development of the foetus, but this obstruction may not arise until after the ascensus medullae spinalis should normally have begun. Thus, according to Holmdahl (1918), is the 23 mm stage.

The ascensus medullae spinalis is not only a passive cranial dislocation of the medulla caused by the columna growing away, as it were, from the medulla. Comparative anatomy shows that the ascensus, to all appearances, is a teleological phenomenon, intended to provide the spinal cord with a better protection in the flexible vertebral canal.

Around the central malformation in spina bifida are grouped other deformities in varying combinations: anomalies of the spinal ganglia and of the vertebrae, incomplete differentiation of the meninges, and deformities in more remote organs (polycystic kidneys, double thumbs, &c). These are parallel phenomena—the expression of a general tendency towards abnormal growth. The question is: what is the genetic connection between, on the one hand, the Arnold Chiari malformation and, on the other hand, spina bifida and hydrocephalus internus?

Arnold (1894) explained the cerebellar malformation as a deformity sui generis, appearing collaterally to spina bifida and caused by a transposition of tissue-elements. Chiari (1895) interpreted the malformation of medulla oblongata as the consequence of congenital hydrocephalus internus in the developing brain. Schwalbe Gredig (1907) declared that the genesis of the Arnold Chiari malformation had not yet been established and that either the deformity may arise independently of spina bifida, or else a causal connection exists so that the spina bifida may (though it need not) cause the Arnold Chiari malformation. van Houweninge Graafdijsk (1932) suggested that the Arnold Chiari malformation is caused through traction on the rhombencephalon by the caudally tethered spinal cord, and thus causes the hydrocephalus by a valvular action in the foramen occipitale magnum. Russell Donald (1935), too, suggested a valvular action by the deformed rhombencephalon, though with a different mechanism. Lichtenstein (1942) attributed to tethering of the spinal cord the Arnold Chiari malformation and stenosis of the mesencephalic aqueduct, and thus, indirectly, internal hydrocephalus.

Professor Russell emphasises that the Arnold Chiari malformation is often found with spina bifida since 1935 "no example of meningocele has been examined without finding an associated Arnold Chiari malformation" (How many examples of meningocele and of other forms of spina bifida have been examined?). Professor Russell's experience may be summarised as follows: (1) in cases of spina bifida with an obstruction of the ascensus medullae spinalis and with hydrocephalus internus, an Arnold Chiari malformation is found often, though not always, (2) in other conditions the Arnold Chiari malformation is found not at all or only very occasionally. Furthermore these rare cases are not unexceptionable, according to Professor Russell herself, however, does

* From the Farmigee Laboratories, Pisa.
1 Russell D S. Observations on the Pathology of Hydrocephalus. Spec Rep Ser med. Res Coun. Lond. no 265. H.M. Stationery Office. See Lancet 1949, i, 920.

not seem to give much weight to this objection, since she uses the cases as arguments against the traction theory. She concludes that this theory cannot be maintained, pointing out, however that at present there is "no alternative theory to offer", it appears probable that the Arnold Chiari malformation takes place at an early stage of embryonic development, perhaps at the stage of closure of the medullary canal, as suggested by Schwalbe Gredig."

In 1941² and 1946⁴ I described two foetal cases of spina bifida with hydrocephalus internus and the Arnold Chiari malformation.

CASE 1—A foetus of 63 mm. Spina bifida partum aperta et partum subcutanea, diastematomyelia thoracica et lumbosacralis, myelocoele thoracolumbalis. The tip of the conus medullaris behind the body of the 3rd sacral vertebra—i.e. at a level normal for the foetal stage, the medullary 2nd cervical segment on a normal level behind dens epistrophei. Hydrocephalus internus. Stenosis of the mesencephalic aqueduct. Malformation of the rhombencephalon with plunging and deformity of the vermis cerebelli (evidently an Arnold malformation at an early stage of development).

CASE 2—A foetus of 115 mm. Spina bifida subcutanea, myelocystocele in the lower part of the back. Accurate calculation of the vertebrae not possible owing to pronounced segmental anomalies. Obviously, however, the ascensus medullae spinalis had been obstructed since the tip of the conus medullaris was on a level with the 3rd vertebra from the caudal end of the spinal column. The medullary 2nd cervical segment on a normal level behind dens epistrophei. Hydrocephalus internus. Deformity of the rhombencephalon with plunging of the cerebellum in much the same way as in case 1.

In each of these two cases we evidently have the initial stage of an Arnold malformation. In one case the ascensus medullae spinalis had not yet asserted itself, and in the other it had not yet appeared in the upper cervical region. Thus, as I pointed out in 1946,⁴ van Houweninge Graaffdijk's traction theory cannot be applied to these two cases. I concluded that the primary cause of the malformation is unknown but is the same factor that causes spina bifida. It is possible that in both my cases an interaction arose at an early foetal stage between hydrocephalus internus and the cerebellum rapidly growing in the posterior fossa. But it is impossible to say which was the earlier abnormality—the hydrocephalus or the cerebellar malformation. It may be supposed that in case 1 the stenosis of the aqueduct first caused the hydrocephalus, but this is, of course, by no means certain.

It should perhaps be emphasised that in these two cases we are dealing with an Arnold but not with a Chiari deformity. Really there is no reason to assume that these two components of the Arnold Chiari malformation must have a common origin. In these two cases, further development traction by the spinal cord (as suggested by van Houweninge Graaffdijk) might perhaps finally have completed the picture by giving rise to a Chiari malformation.

One cannot always dismiss van Houweninge Graaffdijk's traction theory merely because it cannot be applied to some cases. In case 1 the aqueduct stenosis may have been the first visible cause of the deformity of the rest of the hind brain. The origin of a deformity which eventually seems homogeneous may, I believe, vary from case to case within certain limits. One must also take care not to consider the morphogenesis of these malformations simply from a mechanical point of view. The normally growing organism tends, irrespective of accidental external influences, to attain a certain functional form (the "Gestaltungsfunktion" of Roux 1895). This function may be disturbed in case of malformation so that the initially abnormal organism has a propensity towards an anomalous form. This form it endeavours to attain by all available means.

THE PSYCHIATRIC SOCIAL WORKER

SIR,—I should like to endorse Dr Creak's statement last week that the contribution made by psychiatric social workers to mental health is invaluable.

Yet another aspect of their plight has not so far become generally known. I refer to the recent ruling of the Ministry of Health on the classification of these workers for superannuation purposes.

Before the appointed day psychiatric social workers in mental hospitals were classified as class 1 asylum officers with a retiring age of 55 and a contribution to the superannuation fund of 3% of their salaries. After the health service started they were given the option of remaining in the old asylum officers' scheme or joining the National Health Service superannuation scheme, to which they would contribute 6% of their salaries.

No indication was given that the pension would be less and nothing was said to suggest that the retiring age was to be raised. In the event it appears that this is the case. The Ministry of Health has refused to classify psychiatric social workers as mental health officers, which means that many in mental hospitals who decided

to enter the new National Health superannuation scheme will now receive considerably smaller pensions than under the asylum officers' scheme, and at a retiring age of 60. Not only that, but the refusal to classify these workers as mental health officers has at one clean administrative stroke reduced their status to that of the mental hospital clerical worker.

It would seem that the position in the health service of small groups of ancillary workers, possessing no strong political lobby, is sorry indeed.

London SW 5

M POTT

PROTHROMBIN CONSUMPTION DURING MENSES

SIR—Impairment of blood coagulation in women during menses has often been suspected. By means of Quick's¹ consumption test, which has enabled us to detect some latent deficiencies of blood coagulation in various disorders, such as thrombocytopenia,² we have found quite constantly that, in normal women with normal menses, during the menstrual period and especially at its beginning there is a slight but significant reduction of prothrombin consumption, compared with intermenstrual intervals. In many cases the percentage of residual prothrombin 3 hours after coagulation has been about twice as great on the 28th day as on the 14th day. The number of platelets varies inversely with the residual prothrombin.

Slight thrombocytopenia immediately before and at the beginning of the menses has often been described³, this was accurately demonstrated by our co-worker, Rovatti,⁴ and was confirmed by us. The decrease of prothrombin consumption during the menses is, however, greater than would be expected from a simple premenstrual and menstrual diminution in the number of platelets, and this leads us to suspect a functional, transitory insufficiency of platelets (their agglutinability and adhesiveness are diminished during menses), but perhaps during menses there is also deficiency of other coagulation factors.

PSYCHOSOMATIC MEDICINE

SIR,—Professor Pickering's somewhat disingenuous reference to psychosomatic medicine (July 15) has evoked a spate of trenchant replies, of which Dr Halliday's (Sept 2) stands out. But while any physician aware of the interrelationship of mind and body cannot fail to agree with Dr Ellis (Sept 23) that the earliest phase of clinical teaching should emphasise, for example, the importance of anxiety no less than of cancer in the production of anorexia, can such initial emphasis satisfy the student even in his first week of clinical medicine unless it attempts to include some reference to the causes of this anxiety?

It is surely here that a confident working liaison between the teacher who is a general physician and the teacher who is a psychiatrist is indispensable to sound or stimulating teaching. For lack of it may still lead the student to regard anorexia or any other syndrome based on anxiety as a comparatively trivial or even contemptible complaint in contrast to the same condition when due to cancer or some other "real" cause. Encouragement of this attitude of mind by a few general physicians who hold it themselves only aggravates the problem. Yet it is precisely the patient whose basic anxiety is neither superficially reasonable nor capable of resolution by purely common sense measures who

most needs skilled help and understanding, and whose case most needs adequate demonstration and elucidation for the benefit of future practitioners.

Denmark Hill, London S E 5

D STAFFORD CLARK.

Obituary

ERNEST BOSDIN LEECH

M A, M.D. CAMB, HON M A MANC, F.R.C.P., D.P.H.

Dr E Bosdin Leech, consulting physician to the Manchester Royal Infirmary, was the son of Sir Bosdin Leech, a mayor of Manchester who was one of the main promoters of the ship canal and wrote its history, and a nephew of Daniel John Leech, the first professor of pharmacology in the university. He went to school at Cheltenham College, and in 1891 he entered Christ's College, Cambridge. At that time he had thoughts of reading for the Church, but soon he turned to medicine, and four years later he went to the Manchester Royal Infirmary where his uncle was a physician. Qualifying in 1901 he held the usual resident appointments at the infirmary before he set up as a consultant, and when an emergency arose in the resident staff of the infirmary he felt it his duty to give up his consulting rooms and to return as resident medical officer. In this post he gave valuable service in the removal of the infirmary from Piccadilly to the new site in Oxford Road. Shortly afterwards he was appointed to the honorary staff on which he continued to serve until he reached the retiring age in 1938. He was also physician to the Christie Hospital, and he was for many years a most conscientious and respected medical referee under the Workmen's Compensation Act. At the medical school he was an enthusiastic teacher, who knew how to share his enthusiasm with his students. In 1937 the university awarded him the honorary degree of M A.

(P. H. Schmidt)

Leech was president of the Manchester Medical Society in its centenary year. Although his antiquarian knowledge was wide, Manchester, and above all Manchester medical history, was his specialty. His gift to the university medical library of his collection of books and papers on this subject, including his own monographs on Medicine in the Provinces in England, Picturesque Episodes of Manchester Medical History, and Early Medicine and Quackery in Lancashire, was an important and generous contribution. A former president of the Manchester Ancient Monuments Society, he was also a mainstay of the Lancashire Parish Register Society.

E. T. writes: "Bosdin Leech was much more than a good physician. He came of a family which, on both sides, had a great tradition of public service, and this tradition inspired his work and outlook to the end of his life. The social and cultural life of medicine in Manchester owes much to his devoted work. He founded the Cambridge Medical Graduates' Club and the very popular Old Infirmary Residents' Club. He took his full share in the activities of the various medical societies in the town, and whenever a dinner or anniversary or presentation had to be arranged it was always Leech who did the work. He may well be remembered chiefly for his services to the University Medical Library to which he gave many years of devoted work. It is due to Leech that we have so fine an instrument of research in all branches of medicine. His interests were not exclusively medical, and his days of retirement were made happy by a study of the personal and place names of Lancashire and Cheshire and by the publication of parish registers. His motives were ever selfless and without thought of rewards, and he has left his friends many pleasant memories."

Dr Leech married Miss Mary Walder and they had two daughters. He died at his home in Manchester on Sept. 19 at the age of 75.

JOHN CALDERWOOD STRATHEARN

KT, C.B.E., M.D. GLASG., F.F.C.S.E.

Sir John Strathearn, who was for many years warden and chief surgeon of the St John Ophthalmic Hospital in Jerusalem, died at his home near Wimborne on Aug. 15, at the age of 71.

Graduating at Glasgow in 1901, he spent some time in postgraduate study of his chosen specialty in Edinburgh and Berlin. In 1908 he was appointed assistant surgeon at the British Ophthalmic Hospital in Jerusalem, and in 1911 he returned to this country to settle in ophthalmic practice in Dundee where he had been appointed ophthalmic surgeon to the school board and to the education committee of the Fife County Council. In the same year he also took his F.R.C.S.E.

During the 1914-18 war, service with the R.A.M.C. took him once more to the Levant, and for his work there he was appointed O.B.E. in 1918. During the war the old eye hospital in Jerusalem had been destroyed, and Strathearn was chosen as the man to organise the new one. It was a good choice, for he proved an able administrator as well as an excellent surgeon, and the new hospital became his life's work. For many years he was also consultant ophthalmologist to the government of Palestine, and he was promoted C.B.E. in 1928 and knighted in 1938. In a country beset by trachoma his skill as a surgeon was put to good use, and his monograph on the Problem of Blindness in Palestine, published in the *Folia Ophthalmologica Orientalia* in 1933, was both cogent and comprehensive. Though he returned to England in 1940 because of ill health, he continued to work at Goodmayes Emergency Hospital until he retired to Dorset in 1946.

Lord Webb-Johnson, hospitaller of the Order of St John, writes "Sir John Strathearn will always hold an honoured place in the history of the Order of St John. His long devoted, and distinguished services as warden of the Ophthalmic Hospital in Jerusalem added lustre to its annals. The hospital had a tradition of service of over eight centuries before Strathearn joined the staff, but he raised its prestige so that it became a household word throughout the Middle East. The fame of the hospital and its warden spread not only through the Holy Land but through the wider areas of the surrounding countries—into Syria and Transjordan and even across Arabia for the Bedouins also sought advice and treatment. Strathearn's quiet efficiency and operative skill attracted many pupils and secured the adherence of competent assistants while his courteous modesty, patience, sympathy and understanding endeared him to those with whom and for whom he worked. A great citizen of his country, Strathearn was one of whom Britain may well be proud. He was an idealist and he had the urge to serve his fellow men, which his mission in Palestine satisfied. The fame and honour that came to him were fully earned and richly deserved."

GILBERT SMITH

M.D. DURH., F.R.C.S.

Dr Gilbert Smith, who died at Hindhead on June 22, was the second son of Sir Thomas Smith, sometime surgeon extraordinary to Queen Victoria and honorary surgeon to King Edward VII. He was educated at Marlborough and St Bartholomew's Hospital, where he qualified in 1896 at the age of 19. He obtained the F.R.C.S. in 1899, and a year later the M.D. Durh. with a gold medal for his thesis on actinomycosis. He was house-surgeon at Barts to Mr Walsham and clinical assistant in the children's department of the Middlesex Hospital before, in 1900, he joined the late Dr Arnold Lyndon in general practice at Hindhead. The neighbourhood was then coming to be recognised as a health resort and by 1912 the work had so increased that two additional partners had to be taken into the firm. In the first world war Gilbert Smith went to France with the Red Cross and later, in 1917, he joined the R.A.M.C. and worked as a surgical specialist at a base hospital in Rouen.

Gilbert Smith was one of the earliest car owners in Hindhead and a friend recalls the Maberley car which he drove in 1902. It had one wheel in front, one wheel on each side and one wheel behind. The body was S-shaped the driver facing one side of the road his passenger the other. There was no protection of any kind from the weather. The car was belt-driven and the engine being only 2½ h.p. necessitated the passenger

always and the driver often having to dismount on a hill and, walking beside the car, steer it by means of a tiller. A keen sportsman, in his early days at Hindhead he was captain of the golf club. He took his holidays in Scotland and Yorkshire, fishing and shooting.

He married in 1900 Elizabeth Adelaide Carson, who, with four sons and two daughters, survives him.

FRANCIS JAMES STRONG HEANEY

M.A., M.D. DUBL., F.R.C.S.I.

Mr F. J. Strong Heaney, consulting surgeon to the Royal Liverpool United Hospital, died at Christleton, near Chester, on Aug. 26, at the age of 76.

He was educated at Dundalk School and Trinity College Dublin, where he gained the Stewart medical scholarship and graduated B.Ch. in 1901 with honours. After obtaining the higher qualifications of M.D. and F.R.C.S.I., he continued his studies in New York and Paris, and his enthusiasm for the language and literature of France never flagged through a long and busy life.

Strong Heaney joined the R.N.V.R. shortly after he started practice in Liverpool, and he hurried home from his honeymoon in France to join his ship two days before the outbreak of the 1914-18 war. After serving for over two years in H.M.S. *Plassey* he was appointed Admiralty surgeon and agent in Liverpool and on reaching the age-limit he was retired with the rank of surgeon captain.

After the war, he joined the staff of the Liverpool Stanley Hospital and the Liverpool Radium Institute as surgeon. Later he gave his services to the Providence Hospital, St Helens, the Lourdes Hospital, the County Hospital, Ormskirk, and the Queen Victoria Hospital, Morecambe. The University of Liverpool appointed him a clinical lecturer in the early '20s and prolonged his appointment as did the Royal Liverpool United Hospital, until 1946 some ten years after the usual retiring age.

Much of his tireless energy was expended in furthering the interests of his professional brothers. For many years he acted as local secretary of the Royal Medical Benevolent Fund. In the Liverpool Medical Institution he held several time-consuming offices and he was a regular contributor to the scientific discussions. As chairman of the Liverpool Hospital Staffs Association for many years, he proved a persuasive and persevering committee-man and negotiator, and he did much to protect and further the interests of consultants.

To students (writes A. K. W.) Strong Heaney was a patient and kind teacher approachable and very understanding of their difficulties. His massive figure with dangling monocle and enthusiastic shining eye will not easily be forgotten by more than a generation of them. No outpatient clinic was dull when enlivened with his ready wit and his appropriate biblical and classical allusions.

His appointment to the Radium Institute and Cancer Hospital brought many advanced and almost hopeless cases from a wide area under his care. The challenge from these he could not resist and he performed many heroic operations a quarter of a century ago when anaesthesia and resuscitation had not made such procedures commonplace. REGARD for personal reputation and criticism from his more conservative colleagues never made him refuse a bad surgical risk, if he saw a possible chance of curing or alleviating a desperately ill patient. Probably no surgeon in the North of England successfully excised more superior maxillae and tongues in the pre radium era and later for cases in which radiation had failed.

During the early years of the late war when the docks of Liverpool were often a nightly target for the bombers Strong Heaney was a tower of strength in the Stanley Hospital. He never failed to appear shortly after an alert was sounded and with no regard to his age he would operate throughout the night and instil courage and calm into a staff which had every reason to be shaken.

Strong Heaney married Miss Anne McBurner of

to enter the new National Health superannuation scheme will now receive considerably smaller pensions than under the asylum officers' scheme, and at a retiring age of 60. Not only that, but the refusal to classify these workers as mental health officers has at one clean administrative stroke reduced their status to that of the mental hospital clerical worker.

It would seem that the position in the health service of small groups of ancillary workers, possessing no strong political lobby, is sorry indeed.

PROTHROMBIN CONSUMPTION DURING MENSES

SIR,—Impairment of blood coagulation in women during menses has often been suspected. By means of Quick's¹ consumption test, which has enabled us to detect some latent deficiencies of blood coagulation in various disorders, such as thrombocytopenia,² we have found quite constantly that, in normal women with normal menses, during the menstrual period and especially at its beginning there is a slight but significant reduction of prothrombin consumption, compared with intermenstrual intervals. In many cases the percentage of residual prothrombin 3 hours after coagulation has been about twice as great on the 28th day as on the 14th day. The number of platelets varies inversely with the residual prothrombin.

Slight thrombocytopenia immediately before and at the beginning of the menses has often been described³, this was accurately demonstrated by our co worker, Rovatti,⁴ and was confirmed by us. The decrease of prothrombin consumption during the menses is, however, greater than would be expected from a simple premenstrual and menstrual diminution in the number of platelets, and this leads us to suspect a functional, transitory insufficiency of platelets (their agglutinability and adhesiveness are diminished during menses), but perhaps during menses there is also deficiency of other coagulation factors.

PSYCHOSOMATIC MEDICINE

SIR,—Professor Pickering's somewhat disingenuous reference to psychosomatic medicine (July 15) has evoked a spate of trenchant replies, of which Dr Halliday's (Sept 2) stands out. But while any physician aware of the interrelationship of mind and body cannot fail to agree with Dr Ellis (Sept 23) that the earliest phase of clinical teaching should emphasise, for example, the importance of anxiety no less than of cancer in the production of anorexia, can such initial emphasis satisfy the student even in his first week of clinical medicine unless it attempts to include some reference to the causes of this anxiety?

It is surely here that a confident working liaison between the teacher who is a general physician and the teacher who is a psychiatrist is indispensable to sound or stimulating teaching. For lack of it may still lead the student to regard anorexia or any other syndrome based on anxiety as a comparatively trivial or even contemptible complaint in contrast to the same condition when due to cancer or some other "real" cause. Encouragement of this attitude of mind by a few general physicians who hold it themselves only aggravates the problem. Yet it is precisely the patient whose basic anxiety is neither superficially reasonable nor capable of resolution by purely common sense measures who

most needs skilled help and understanding, and whose case most needs adequate demonstration and elucidation for the benefit of future practitioners.

Obituary

ERNEST BOSDIN LEECH

M.A., M.D. CAMB., HON. M.A. MANC., F.R.C.P., D.P.H.

Dr E. Bosdin Leech, consulting physician to the Manchester Royal Infirmary, was the son of Sir Bosdin Leech, a mayor of Manchester who was one of the main promoters of the ship canal and wrote its history, and a nephew of Daniel John Leech, the first professor of pharmacology in the university. He went to school at Cheltenham College, and in 1894 he entered Christ's College, Cambridge. At that time he had thoughts of reading for the Church, but soon he turned to medicine, and four years later he went to the Manchester Royal Infirmary, where his uncle was a physician. Qualifying in 1901 he held the usual resident appointments at the infirmary before he set up as a consultant, and when an emergency arose in the resident staff of the infirmary he felt it his duty to give up his consulting-rooms and to return as resident medical officer. In this post he gave valuable service in the removal of the infirmary from Piccadilly to the new site in Oxford Road. Shortly afterwards he was appointed to the honorary staff on which he continued to serve until he reached the retiring age in 1938. He was also physician to the Christie Hospital, and he was for many years a most conscientious and respected medical referee under the Workmen's Compensation Act. At the medical school he was an enthusiastic teacher, who knew how to share his enthusiasm with his students. In 1937 the university awarded him the honorary degree of M.A.

Leech was president of the Manchester Medical Society in its centenary year. Although his antiquarian knowledge was wide, Manchester, and above all Manchester medical history, was his specialty. His gift to the university medical library of his collection of books and papers on this subject, including his own monographs on *Medicine in the Provinces in England*, *Picturesque Episodes of Manchester Medical History*, and *Early Medicine and Quackery in Lancashire*, was an important and generous contribution. A former president of the Manchester Ancient Monuments Society, he was also a mainstay of the Lancashire Parish Register Society.

E. T. writes: "Bosdin Leech was much more than a good physician. He came of a family which, on both sides, had a great tradition of public service, and this tradition inspired his work and outlook to the end of his life. The social and cultural life of medicine in Manchester owes much to his devoted work. He founded the Cambridge Medical Graduates' Club and the very popular Old Infirmary Residents' Club. He took his full share in the activities of the various medical societies in the town, and whenever a dinner or anniversary or presentation had to be arranged it was always Leech who did the work. He may well be remembered chiefly for his services to the University Medical Library to which he gave many years of devoted work. It is due to Leech that we have so fine an instrument of research in all branches of medicine. His interests were not exclusively medical, and his days of retirement were made happy by a study of the personal and place names of Lancashire and Cheshire and by the publication of parish registers. His motives were ever selfless and without thought of rewards, and he has left his friends many pleasant memories."

Dr Leech married Miss Mary Walder and they had two daughters. He died at his home in Manchester on Sept. 19 at the age of 75.

Notes and News

RESEARCH DEFENCE SOCIETY

IN 1913 this society began publishing an 8-page quarterly report which in 1921 became its official journal with the name of *The Fight Against Disease*. Since then great advances have been made in the control of disease and the committee of the society have decided that in future their journal shall be known as *Conquest*. Its first issue under this new title has appeared, and in his editorial Dr J. D. Robertson holds out the hope that the journal will now be printed quarterly, as before the war, or even every two months. The striking new cover has been designed by Mr R. S. Sherriffs and the first issue contains an article on the Conquest of Pain—the Story of Anaesthesia by Dr C. J. Massey Dawkins and one by Dr E. S. Duthie on Chemotherapy and Antibiotics in the Control of Disease. The journal which is free to members of the society, may be obtained (2s. 6d.) from the office of the society, 11, Chandos Street, London, W.1.

ALCOHOLISM IN FRANCE

EVER since the reign of Louis XIV the French have had the reputation of appreciating quality rather than quantity in eating and drinking. Prof. Paul Perrin,¹ however, gives a different picture. French doctors, it seems, are perturbed by the increase in drinking since the war, and Dr Perrin, who is professor of medicine at Nantes and heads the Groupe Médical d'Études Anti-alcooliques, has investigated this. He wrote to 1667 medical colleagues 93% of whom agreed that the problem was grave. The Frenchman, it is estimated, drinks 6 times as much alcohol yearly as the Englishman and nearly 15 times as much as the Norwegian. Before the war he was drinking nearly 3 times as much wine as he did in 1880 and in the intervening period the number of licences had doubled. Though France produces nearly half the wine in the world, she imports 3½ times as much alcohol as she exports. In Lyons, according to Professor Perrin, 47% of hospital admissions are attributable to alcoholism, 75% of venereal-disease infections occur under the influence of drink and in the west of France alcoholism was thought to be a cause of 30–50% of admissions to mental hospitals.

The theme of Professor Perrin's book, then, is that alcoholism contributes largely to venereal disease, tuberculosis, mental disorders and road deaths and that it is a greater scourge than cancer. Yet the ordinary man is still complacent about it; he believes that wine and beer coming from good grapes or barley, are good foods. In Great Britain, as in France, enormous sums are spent in persuading us that it is mainly to drink and that alcohol makes us more efficient. Social prejudices too encourage drinking, many believing that it is bad manners to refuse a drink in company and that wine is indispensable for any celebration.

Professor Perrin shows that during the occupation of France the fall in the consumption of alcohol produced a vast amelioration of evils due to alcoholism. One of his chief points is that alcoholism is not, as suggested by some eminent psychiatrists, merely a symptom of a psychopathic disposition which would find expression in some other way even if the patient did not drink. There are French villages where 70–80% of the male population is alcoholic and one can hardly suppose that so high a proportion would be psychopathic. Psychiatrists have paid too little attention to the environmental factor: there are too many social milieus in which people feel compelled for social reasons to drink habitually to excess. Professor Perrin therefore urges those who occupy positions of prestige to remain abstinent as long as alcoholism remains the scourge which it is at present.

His other suggestions for combating the evil include instruction of the young, reduction of licences, withdrawal of licences from general stores, abolition of slums and the encouragement of sports as well as the manufacture of agreeable soft drinks. His hope is that more Frenchmen will follow the example of Pasteur, who preferred to drink his wine while it was still in the grape. He is on less sure ground and much less convincing when he describes a "plot" in Washington to prevent the Prohibition laws from being enforced, thus causing them to fail, when he insists that the sperm is injured by alcohol so that the children of alcoholics

are degenerate and when he advocates Lecoq's treatment of alcoholism with intravenous alcohol, which has not found favour outside France. But these are the pyrotechnics of the enthusiast and do not detract from the importance of his main theme.

THE DOCTOR AND THE LIBRARY

THE library as the tool of medicine—and its possible misuse—was the theme of a symposium held by the medical section of the Library Association in London on Sept. 20, with Mr W. R. LE FANT, president of the section and librarian of the Royal College of Surgeons of England, in the chair. Sir Cecil Wakeley, F.R.C.S., said many attempts had been made to co-ordinate the work of medical libraries. Sir William Osler had founded a short-lived association of medical libraries. Years later in his turn Sir D. Argy Power promoted a measure of co-operation among the larger medical libraries in London. The Royal Society of Medicine had also made its contribution through the Central Medical Library Bureau which it organised with the help of the Rockefeller Foundation and which served, among its other duties, as a clearing house for readers' inquiries. The usefulness of the medical section of the Library Association had also proved itself. Its membership now ran into hundreds; it had produced a scheme for medical libraries in hospitals and it had a pool for journals. "But the real need," Sir Cecil declared, "is for the medical profession to decide what it wants from its libraries."

Dr C. H. KILLAWAY, F.R.S., director of the Wellcome Research Institution, pointed out that in a research institution the library performed a valuable service by providing a survey of the literature for the worker, but care should be taken that the young worker was not overwhelmed with too great a mass.

Dr HUGH CLEGG, editor of the *British Medical Journal*, was sure that the medical librarian must be more than a mere cataloguer. He must have a wide knowledge of medical literature and a trustworthy appreciation of sources—in fact he must be an information officer. In a warning reference to "sheets of bibliographies" attached to papers Dr Clegg remarked: "In my innocence I once believed that every paper in these bibliographies had at least been dipped into by the author. The librarian must have the courage to say: 'Is your bibliography really necessary?' Mr L. T. Morton had prepared for Unesco a world list of journals, abbreviations and abstracting services which, when published, would be invaluable."

Mr V. ZACHARY COPE agreed that trained medical librarians were essential. But use of the library was accompanied by abuse and he often felt sad when he heard young men asking for bibliographies. Many people were losing a valuable part of their education in not looking up their own references.

Mr. GEOFFREY STEPHENS explained that each London borough specialised in one branch of knowledge so that over the whole area no book of importance, however expensive, would not be available in one of the public libraries. His own library of St. Marblebone had been chosen for the medical section. Mr A. J. FIELDER, chairman of the Stames group, hospital management committee, felt that the regional board should co-ordinate any special library provision. Mr W. J. BISHOP, secretary of the section and librarian of the Wellcome Historical Library, also supported the view that a public library while it might carry literature for students, could not properly provide a general medical library.

1949 IN REVIEW

SOME will remember 1949 as the year in which Middlesex and Yorkshire tied for the county cricket championship, some because for a few short weeks sweets were freed from rationing and still others for the 30% devaluation of sterling on Sept. 18. These and a host of other events domestic and foreign, grave and gay, are faithfully recorded in the latest *Britannica Book of the Year*. Into just over 700 pages 492 authors have crammed well-documented accounts of what passed. Of the 752 entries, one of the most depressing is that concerned with new words for in this company we find "bonusable," "disincentive," "dis-saver," "down turn" (for reduction or falling off in amount &c.), "in-er-ven-or" and "redundantize" yet perhaps one day even these will be embraced by the Oxford editors. The volume which is well printed and amply illustrated, would be welcomed at Christmas by anyone who likes to be sure of his recent history.

Dr MORLEY FLETCHER

D H writes "A memorial service was held in the fine old church of Petworth on Sept 13, when the Bishop of Rochester delivered a remarkable address. He said 'All who knew Dr Fletcher (and to know him was to love him) drew strength and confidence from his serene yet dynamic vitality. He so enjoyed life—every moment of it, and God blessed him with a long life, crammed with service and lived with zest'."

"By some unknown magic Morley Fletcher never became old. When he was over 80, his motor insurance company questioned whether they could cover him any longer, and the young man that came to interview him, after listening for some time to his arguments, said 'It is not you I came to interview, I hoped to see your father'! Fletcher was singularly fortunate and had innumerable friends. At Barts he was popular with all. Everyone recognised his rare gifts. He was always ready to give good advice not only in medicine but also on a wide range of other subjects. Nothing was too much trouble. Thus he once went all the way to Norfolk to see a colleague's child, who was not so very ill, and refused to accept any kind of reward, not even his travelling expenses. There must be many old students who can remember similar kindnesses given without any thoughts of himself. He had a grand personality, a great life—every minute of which he enjoyed. May God bless him."

Public Health

Poliomyelitis

IN the week ended Sept 16 notifications of poliomyelitis in England and Wales were paralytic 291 (327), non-paralytic 187 (186), total 478 (513). The figures for the previous week are shown in parentheses. The total decrease compared with the preceding week was 35, all but one of which represented paralytic cases. Non-paralytic cases in the week under review comprised 39.1% of the total. The uncorrected notifications for the corresponding week in 1947, 1948, and 1949 were 614, 74, and 342.

The counties showing the most significant decreases were the West Riding of Yorkshire, Warwick, and Stafford with 16, 10, and 10 fewer cases. Maternal increases were recorded in Worcester (12) and Dorset (6). No county area has been free of infection during the six weeks up to and including Sept 16, but only 1 case has been notified in Anglesey and Cambridge, and there have been only 2 cases in the Isle of Ely and Radnor.

The total of notifications for 1950 up to and including the week under review was 5604. The corresponding figures for 1947, 1948, and 1949 were 5598, 1288, and 2989.

University of Oxford

On Oct 12 the Osler medal will be presented to Sir Ernest Kennaway, F.R.S., for his work in cancer research

University of Sheffield

On Sept 23, the following degrees were conferred

M.B.B.S.—Horace Bailey, Patricia T. Ferraro, W. E. Freeman, L. G. Gordon, Shelagh Hannath, E. A. Johnson, F. E. Neal, N. L. Sarkar, J. D. Warren.

Dr R. F. Crampton has been appointed assistant lecturer in physiology

Royal Medico-Psychological Association

Prof A. J. Lewis will deliver the 25th Maudsley lecture at 1, Wimpole Street, London, W.1, on Friday, Nov 17, at 2.15 p.m. He has chosen as his subject Henry Maudsley, His Work and Influence

W.H.O. Mission to Korea

A W.H.O. mission to Korea, under the direction of Colonel W. H. Crichton, is to help reorganise health services, and to assist in relief programmes and in the control and prevention of communicable diseases

Caldecote Hall

The Church of England Temperance Society and National Police Court Mission inform us that they are shortly appointing a resident medical superintendent, in succession to the late Dr A. E. Carver, at this home for nervous and addiction cases. Meanwhile the hall remains open under the charge of a qualified sister and is regularly visited by a doctor

Friends of Vellore

To celebrate the golden jubilee of the Christian Medical College at Vellore, South India, a meeting is being held at the Caxton Hall, Westminster, London, S.W.1, on Thursday, Oct 12, at 3 p.m., when the speakers will include Dr Sarah Joseph of the Vellore staff. The Vellore film will be shown at 5 p.m. At 5.30 p.m. Sir George McRobert, F.R.C.P., will take the chair at a medical meeting which will be addressed by Dr L. Chacko, Dr J. Donald Ball, and Sir Henry Holland, F.R.C.S. Tickets may be had from Miss Marjorie Chapman, secretary of the Friends of Vellore, Annandale, North End Road, N.W.11

A Recovery Home

The Birmingham Regional Hospital Board have been asked to approve the use of beds at Little Bromwich Hospital—a large and well equipped infectious-diseases hospital—for recovery cases. In the region nearly 60,000 people are waiting for beds, and it is thought that some 20,000 who have only minor ailments could well be transferred, after a short period of intensive treatment at a parent hospital, to Little Bromwich Hospital. The acute hospitals can provide medical and surgical facilities for these cases, but the pressure of urgent cases on their beds is so great that they cannot afford to block them with patients who are recovering from the treatment of minor ailments

Courses in the Management of Domestic Staff

The Ministry of Health, by arrangement with the council of Morley College and in co-operation with the Institute of Personnel Management and the Institutional Management Association, is organising at Morley College, London, S.E.1, a series of 11 week non residential courses in staff management for those engaged in domestic administration. During the present session courses will be held from Jan 1 to March 16 and from April 16 to June 29. Most of the places will be allocated to candidates from the hospital service nominated by their hospital management committee or board of governors. Officers who are interested in the courses should consult their committee or board and not the Ministry of Health

"Vitamin P"

At a meeting of the Federation of American Societies for Experimental Biology in Atlantic City in April, the following recommendation of the joint committee on biochemical nomenclature of the American Society of Biological Chemists and the American Institute of Nutrition was adopted

The term vitamin P was first applied to a substance present in lemon juice. It was said to be effective in reducing the extent of hemorrhages and extending the duration of life in scurvy guinea pigs and was also proposed for the treatment of vascular purpura. Subsequent studies have failed to substantiate these claims and the identity of a substance of a vitamin nature has not been established. Continued application of the term vitamin P to one or another of a group of polyphenolic substances will lead only to confusion. It is therefore recommended that the term 'vitamin P' should no longer be employed.

Sex-hormone Preparations

Manufacturers announce substantial reductions in the price of these products next week.

Charing Cross Hospital

Dr Gordon Holmes, F.R.S., will give the inaugural address at this hospital on Thursday, Oct 6, at 4 p.m.

Welsh National School of Medicine

Prof A. D. Macdonald will give the opening sessional address of this school on Thursday, Oct 5

International Hospital Congress

The second post-war congress arranged by the International Hospital Federation will be held in Brussels from July 15 to 21 1951, on the Care of the Chronic Sick and the Aged

Royal Institute of Public Health and Hygiene

Popular lectures on subjects relating to the public health will be delivered at the institute, 28, Portland Place, London, W.1, at 3.30 p.m. on Wednesdays, from Oct 18 to Nov 29

Lloyd Roberts Lecture

Sir William Fletcher Shaw will give the 21st Lloyd Roberts lecture at St Mary's Hospital, Whitworth Street West, Manchester, on Tuesday, Oct 10, at 4.30 p.m. He is to speak on the Birth of a College

Research Defence Society

Prof E. D. Adrian, O.M., F.R.S., will deliver the Stephen Paget lecture on Wednesday, Nov 22, at 5.30 p.m., at University College, Gower Street, London, W.C.1. He has chosen as his subject Experiments on the Nervous System

St Thomas's Hospital

The old students' dinner will take place at Claridges Hotel, Brook Street, London, W.1, on Friday, Oct 20, at 7.30 p.m. Dr J. P. Hedley will be in the chair. Tickets (30s.) may be had from the hon. secretaries, St Thomas's Hospital, S.E.1

French Congress of Gynaecology

To celebrate its jubilee the Société Française de Gynécologie is holding an international conference at Paris from June 23 to 29 1951. Further particulars may be had from M. Maurice Fabre, 1, rue Jules Lefebvre, Paris, 9

Hormone to Increase Lamb Production

Ewes receiving injections of gonadotropin have been found to lamb twice in a single year. This, the *New York Times* (Sept 18) reports, has been established by a team sponsored by Armour & Co., of Chicago. A representative of this firm has estimated that from 100 ewes an additional 65-85 lambs may be obtained in the extra "fall crop"

Isle of Man Health Service

The *Times* (Sept 20) reports that amendments to the National Health Act have been passed in the Manx legislature providing that patients in the Isle of Man in future will have to pay their doctor 6d for a form on which prescriptions are written. They will also have to take their own container for medicine to the chemist, and pay a dentist a tenth of their account after the first pound. The original estimates for the Manx service, which were sent back for revision, came to £800,000. A ceiling of £600,000 has now been placed on expenditure for this year, and the amendments have been made for economy

The British Standards Institution has issued draft standards for rubber ward dressing gloves and porters gloves for hospital use, for rubber post-mortem gloves, for graduated beakers for injectable fluids in hospitals, and for stainless steel hospital operating theatre and ward holloware

Tropical Ulcer is dealt with in bulletin no. 4 of the Ross Institute industrial advisory committee. Copies of this and of earlier bulletins are obtainable from L. G. Ponsford, organising secretary, the Ross Institute of Tropical Hygiene, London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1

A brochure illustrating the equipment available from British sources for isotope techniques in medicine, research, and industry has been produced by the Scientific Instrument Manufacturers' Association in collaboration with the Atomic Energy Research Establishment, Harwell. Copies may be had without charge, from the association, 17, Princes Gate, London, S.W.7

Founded 1823 PUBLISHED WEEKLY Registered as a Newspaper

Pp 8—Price 1s
Annual Subscription
£2 2s

As originally planned, this issue was to have 54 pages of text. Their number was successively reduced to 40 and 36, and we now present a residual 8. Nor are all of them those we should have chosen had our choice been free. We can only beg our readers to remain indulgent during the further weeks, months, or years required for settlement of the dispute that is again immobilising London printers.

Hæmagglutination Test for Tuberculosis

A SEROLOGICAL test for tuberculous infection as reliable as the Wassermann reaction in syphilis would be of immense value to the clinician, but despite the multitude of agglutination, complement fixation, and precipitin methods devised in the last 50 years none has proved wholly satisfactory. Two years ago MIDDLEBROOK and DUBOS¹ introduced a hæmagglutination test which they claimed could detect small amounts of antibody produced against one or more of the polysaccharide antigens in mammalian strains of the tubercle bacillus. Washed red cells from the sheep are sensitised with an active antigenic fraction from an extract of the tubercle bacillus or from commercial preparations of old tuberculin. The sensitised cells are then added to dilutions of inactivated serum from the patient, if the test is positive the sheep cells are agglutinated and when shaken appear as clumps in the supernatant fluid. A complication is that all heterophile antibody must be removed from the serum before adding it to the sensitised cells.

The Middlebrook-Dubos test has been tried by several workers here and in France, and ROTHBARD² and associates in the United States obtained negative results in 203 of 216 non-tuberculous patients, whereas 155 out of 168 cases of active tuberculosis gave positive hæmagglutination in titres of 1/8 to 1/512. Monthly tests on 120 tuberculous patients showed a gradual disappearance of antibodies with clinical improvement. These findings suggest that the test would be highly valuable in active tuberculosis but those of SMITH and SCOTT³ are less encouraging. They found agglutinins in 83 out of 104 sera from phthisical patients with tubercle bacilli in the sputum and in 6 whose sputum was clear, the negative sera mostly coming from patients with advanced disease and a poor prognosis. Most of the few tests done on patients with arrested tuberculosis were negative, as were 18 out of 22 on syphilitic patients. They have also investigated the relation of the test to tuberculin sensitivity. Half of 70 healthy tuberculin positive people gave positive hæmagglutination reactions, and nearly a third of 68 healthy students developed hæmagglutinins after their first tuberculin test. Similarly, out of 13 students inoculated with BCG, 10 developed hæmagglutinins, though all 13 gave positive tuberculin reactions.

The finding of hæmagglutinin clearly does not prove that active infection is present, though MIDDLEBROOK⁴ suggests that with a reliable antigen a serum titre of 1/8 or higher is presumptive evidence of disease caused by the tubercle bacillus or an antigenically related mycobacterium. Apparently the reaction does not measure either the patient's resistance to tuberculosis or

the activity of the tuberculous process, and the possibility of false positive or false negative reactions has yet to be eliminated. For the present, at least, the test will not take the place of isolation and identification of the infecting organism, which in tuberculosis, as in other infectious diseases, is by far the surest method of diagnosis.

Annotations

THE REPRESENTATIVE MEETING

Two urgent problems facing the British Medical Association—first the work and status of the general practitioner and secondly the position of the association itself in these changed days—were brought into sharp relief last week when the annual meeting of representatives, adjourned from Southport,¹ was completed in London.

The association will evidently have a stiff fight in its campaign to gain more beds for general practitioners. A North Country representative reported continuing displacement of practitioners from hospital posts, while a London spokesman said that in his area, though the work of hospitals could not be carried through without the continuing help of G.P. clinical assistants, their future was still in doubt. At the meeting the most stringent criticism was reserved however, for the report on the G.P.'s training.² It was argued that the proposed three years postgraduate training would deter people from entering practice and might impose a heavy financial burden. Furthermore, if he did study for these extra years, the practitioner should gain an income more in keeping with the specialists. Dr J. C. Arthur declared that what the young doctor needed was not more training but more confidence to apply the knowledge he had already gained, and if he was to enter practice with this added confidence his teachers must undergo a change of heart. More than one representative feared that the Cohen report's insistence on these further years might become the basis of action by the Ministry of Health. Let us not, as one put it, "give the Minister another chain to fetter us." Sir Henry Cohen retorted that the best practitioners already put in the extra period of study and the report was concerned not with politics but with education. His answer did nothing to still the prevalent disquiet. Alive to the Minister's enhanced powers, representatives are loath to give grounds for action which might in the end prove unwelcome to many in the profession. With firm rooting of this fear constructive endeavour might be brought almost to a halt.

TRANSPOSING THE ULNAR NERVE

FROM a study of 46 cases treated at the Wingfield Morris Orthopaedic Hospital McGowan³ confirms the impression that in cases of traumatic ulnar neuritis and late ulnar palsy one can safely promise that anterior transposition of the nerve will prevent any further sensory or motor deterioration in the hand but one cannot guarantee any actual recovery. In 21 of her patients the symptoms had developed years after a fracture near the elbow, in 10 they were associated with osteoarthritis of the joint (most of these patients were right handed labourers affected on the right side), and in 3 there was recurrent dislocation of the nerve. In 2 patients there was congenital cubitus valgus and dislocation of the head of the radius in another 3 there was local scarring after soft tissue laceration, while in the remaining 7 no obvious primary abnormality could be found. When the clinical features of ulnar neuritis were slight at the time of operation—i.e., when there was no detectable motor weakness and only mild sensory disturbance—there was rapid complete functional recovery. In the intermediate group, with intrinsic wasting and weakness and some anaesthesia or analgesia in the hand, though

the hand became strong and useful and free from discomfort after the operation, slight residual weakness persisted in over half the cases and some sensory impairment in a quarter. In the severe lesions with gross interosseous paralysis, full motor recovery was seldom obtained. Nevertheless, the results fully justified operation, there was always some muscle improvement the function of the hand as a whole was much better, and sensation became more normal even when anaesthesia or analgesia had been conspicuous.

Evidently the operation should not be delayed if adequate return of power is wished for, and even the most advanced cases can be confidently expected to gain considerably from operation. It cannot be assumed that progressive deterioration is inevitable in the untreated case, for McGowan records that one patient, who refused operation, made a complete spontaneous recovery after 2½ years, but this is so unlikely that operation is always advisable. As Brooks⁴ says, "there is no conservative treatment."

TREATMENT OF CEREBRAL PALSY

In young people the relief of cerebral palsy depends mainly on re-education. For teacher and taught this is a heavy undertaking, but so far no other form of treatment has been of much help. Sustained medication with the muscle relaxant, mephenesin ('Myanesein') has been tried by Frantz.⁵ Spasticity was relieved little if at all, but of 16 children with athetosis 14 were clearly benefited. A surgical method of increasing cerebral circulation has been explored by McKhann and colleagues⁶ in Cleveland. In 125 cases they anastomosed the common or external carotid artery with the internal jugular vein, and they noted improvement in about 35% of children with cerebral palsy, mental retardation, or convulsive disorders, and in a small proportion of adults with cerebral vascular accidents and other complications of arteriosclerosis. The procedure is reversible and seems to be relatively safe, but its imitators suggest that it deserves study as a new approach rather than as a satisfactory solution.

TOWARDS SAFER MILK

THE area eradication scheme, which began to operate at the beginning of this month, is designed to hasten reduction in the proportion of cattle infected with the tubercle bacillus, so that in fifteen years or so our dairy herds will include no reactors. Immediate slaughter of all reactors is not feasible, because it would cause a disastrous fall in milk supplies and serious disturbance of farm economy, the cow plays an important part in maintaining soil fertility, and some replacement stock must be bred from the tuberculin positive.⁷ Instead, selected areas, beginning in October 1952, with two of the "cleanest"—in south west Scotland and in south west Wales—are to be declared eradication areas. There reactors will be slaughtered and compensation paid, and movement of cattle into these areas will be controlled, meanwhile, testing of herds is being offered without charge. In two further areas—the Scilly Isles and the Shetland Islands—all cattle are already attested. Throughout the land only about 22% of all cattle are in attested herds.

Reliable tuberculin testing will now be more than ever necessary, and there are indications that at present the results do not deserve implicit faith. Disquiet has been caused because positive results are sometimes obtained in animals which belong to home-bred herds and which, on slaughter, show no signs of tuberculosis. Misleading results may sometimes be due to a mild acid fast bacillary infection of the skin the pathology of which is uncertain. Obscure infection of this sort is apparently not confined to animals, for acid fast and alcohol fast bacilli, unidentifiable by ordinary methods, have been recovered from patients with urinary infection.

As the eradication scheme develops, the effect on the incidence of pulmonary tuberculosis in man may prove unexpectedly striking, for studies in Scandinavia have shown that in rural areas as many as half the cases of phthisis may be due to the bovine organism.⁸

HOSPITALS AND THE PRESS

At its annual conference in London last month the Institute of Journalists unanimously adopted a resolution deploring "an increasing tendency for officialdom and 'red tape,' particularly in nationalised organisations, to impede the public services of the press", and almost every speaker spoke most harshly of the hospitals. Mr V S Halton claimed that when these depended on the press for much of their income they always co-operated with newspapers, and it was possible at any time to go in and get the names of people involved in accidents. "Now, under nationalisation, there is no time for the press, and the normal avenues of information are closed." Mr S Wadlake agreed that the atmosphere previously cordial, had changed with the start of the National Health Service.

Doctors are trained to shun personal publicity. Moreover, they are constantly aware of their duty to preserve the confidential relation between themselves and their patients and they are sometimes in doubt of the use to which information they give will be put. Hospitals, they rightly feel, exist to help and protect patients, whose misfortunes should not be regarded as 'news'. On the other hand, sometimes they are clearly bound not to withhold the facts. Thus the Minister of Health¹ has suggested that, when there is a big accident, the public is entitled to know its extent and—after the relatives have been notified—the names of the injured. Otherwise, the Minister has wisely left hospitals to decide their own public relations policy. Often, however, no policy exists, and the amount of information given depends on the doctor who receives the inquiry. Hospitals might be wise therefore to invite local editors and their own staff to a meeting at which a policy could be worked out, and to appoint a public relations officer—perhaps the medical superintendent where there is one—to see that this is pursued. All will wish to preserve as much as possible of the local pride and local interest which newspapers can help to engender.

MAKING THE MOST OF OUR CONGRESSES

THE Council for the Co-ordination of International Congresses of Medical Sciences, which is sponsored by WHO and UNESCO, have now completed their first year's work. With their comprehensive advance information and tactful synthesising powers, the council have been able to arrange for many related congresses to be held in the same town within a few days of each other. Many workers have thus been able to make a fuller use of their visits abroad. The council have also been able to help the organisers of related congresses to draw up programmes which did not cover the same ground, and to provide suitable background courses for those attending the congresses. The council's *Bulletin* may be obtained from UNESCO House, 19, Avenue Kléber, Paris, XVI, and the April-July issue for this year contains a useful list of congresses which are to be held as far ahead as 1953.

THE STATE AND MEDICINE

In his inaugural address to King's College Hospital Medical School on Sept. 28, Sir Lionel Whitby expressed his belief that as the cost of a serious illness is now beyond the purse of an ordinary person, all civilised nations will sooner or later be obliged to set up some form of subsidised medical service, and experience seems to show that even a partial subsidy must be so large that in practice the scheme must be handled by the State. In his view medical men should therefore not oppose a State service, for it is inevitable, but rather give their minds to ensuring that individualism, which has done so much for medicine in the past, is not extinguished by too much insistence on plans and planning.

Dr S. Roodhouse Gloyne, pathologist to the London Chest Hospital from 1911 to 1948, died in London on Sept. 25.

THE INDEX and title page to Vol. I, 1950, which was completed with THE LANCET of June 24, is published with our present issue. A copy will be sent gratis to subscribers on receipt of a postcard addressed to the Manager of THE LANCET, 7, Adam Street Adelphi, W.C.2. Subscribers who have not already indicated their desire to receive indexes regularly as published should do so now.

Reviews of Books

British Encyclopædia of Medical Practice

(2nd ed.) Editor Lord HORDER, F.R.C.P., consulting physician, St Bartholomew's Hospital London. London Butterworth 1950 Vols I and II Pp 719 711 £3 per volume

THE first edition of this work, in which diseases are considered alphabetically began to appear in 1936 and under the editorship of Sir Humphry Rolleston the end of the alphabet was reached at the start of the late war in 1939. In these four years the *Encyclopædia* gained a reputation for truly covering medical disorders from A to Z, and Lord Horder, who is now the general editor has wisely retained the same layout. Nowadays those who contribute to or edit, such works as this often find to their chagrin that the information is partly outdated even before it is printed, but the collection from time to time of authoritative and comprehensive accounts provides a milestone by which to mark further progress and the popularity of this particular work reflects its daily usefulness to practitioners.

Biological Actions of the Adenine Compounds

H. N. GREEN, M.A., M.D., M.Sc. professor of pathology, University of Sheffield. H. B. STONER, M.D. B.Sc. research assistant in the department. London H. K. Lewis 1950 Pp 222 25s.

Professor Green and Dr. Stoner describe investigations undertaken to assess the significance of their original observation in 1943 that adenosine triphosphate (A.T.P.) is responsible for nearly the whole of the 'shock' inducing effect of fresh skeletal muscle extract, when injected by routes other than the intravenous. After reviewing the chemistry of the adenine nucleotides and the metabolism of A.T.P. they describe in detail the effect of the purine derivatives on the cardiovascular and respiratory systems, the potentiating effect of magnesium ions, the relation between pulmonary embolism and the effect of A.T.P., and the effect of certain therapeutic agents on A.T.P. shock. They conclude with a discussion of the possible rôle of nucleotides in various pathological states. Their monograph is an impressive record of wide-ranging inquiries which (to quote Sir Edward Mellanby's foreword) should be of interest to biologists in general because it embraces most of our present knowledge of the effects produced by the presence of A.T.P. and related compounds in extracellular sites. Though mainly an account of a particular series of experiments it surveys the relevant literature and is therefore a useful reference book.

The Rheumatic Diseases

(3rd ed.) G. D. KERSLEY, M.D. Camb. F.R.C.P., physician with care of rheumatic diseases, Bristol Royal Hospital physician to the Royal National Hospital for Rheumatic Diseases Bath. London Heinemann 1950 Pp 143 15s.

THIS book now embraces the "new rheumatology", for, while it starts with conventional chapters introducing and classifying rheumatic conditions, it reaches endocrinology in the third chapter. The first illustration is that of steroid formulae and the second displays the action and uses of A.C.T.H. and 'Cortisone'.

A short chapter covers rheumatic fever. The account of rheumatoid arthritis is well illustrated and up to date: the value of various forms of treatment is discussed in a critical and constructive way, and though the use of cortical steroids is wisely omitted from the section on therapy the investigations now in progress are of course mentioned. Specific infective arthritis is briefly but adequately described but osteoarthritis is dismissed surprisingly quickly. Not all orthopedic surgeons would agree that where the hip is affected in ankylosing spondylitis, arthroplasty "is usually only temporarily satisfactory". Gout is fully covered, and treatment including hydrotherapy is gone into in some detail. Dr. Kersley thinks that fibrositis does in fact exist in spite of its at present somewhat undefined pathology. The mechanism of muscular pain and the various theories of its causation are described with copious reference to the literature. It is somewhat surprising to see Bell's palsy included in the chapter on fibrositis and to find that the old-fashioned wire splint extending from the ear to the corner

of the mouth is still advocated. While sciatica receives a chapter of its own brachial neuritis gets only a paragraph in the one on fibrositis. The last chapter covers special 'treatments', ranging from dietetics through hydrotherapy, X-ray therapy, and physiotherapy to surgery. While there is much good sense and a rational approach to all the methods included the subject cannot be satisfactorily presented in so small a space.

Surgery of Repair

JOHN F. PICK, S.B., M.M. M.D., F.R.C.S. clinical assistant professor of surgery, University of Illinois. Philadelphia and London J. B. Lippincott 1949 Pp 328 £9 9s. the set.

THESE two volumes make a useful addition to the surgeon's library. Perhaps rather too much (some 180 pages) of vol. I is taken up with theoretical and philosophical considerations. Next, the early treatment of a damaged part is considered, with due attention to repair of bones, blood-vessels, and nerves, and to early skin covering. Then the varieties of skin transplantation are described not forgetting homografts in their restricted application: tube pedicles and flaps are discussed in some detail. The treatment of scars and burns is dealt with in a general way: grafts of tissues other than skin are described, and a chapter on "surgical geometrics" is especially useful, though some of the diagrams must be interpreted with caution. The second volume is regional, taking in turn the different parts of the body and the methods available for repair. An extensive section covers mandibular injuries and deformities and there is a good section on the ear. In fact few problems in reparative surgery escape mention. As in most American books, the bibliography is enormous and the whole work is profusely illustrated.

Letters to the Editor

TUBERCULIN SURVEYS

SIR,—In a recent tuberculin survey of 1 girls' grammar school in a London suburb conducted by one of us (A. G. H.), the proportion of negative reactors was found to be 76%. The ages of the pupils ranged from 12 to 19 years and the level of tuberculinisation was remarkably uniform in each year—it was not significantly higher in the later age groups. The flour paper jelly technique was employed, and possibly complete Mantoux testing up to 1:100, might have shown a slight increase in the proportion of positive reactors, but it would appear that between two thirds and three quarters of the girls have not as yet experienced their primary infection. As it is probable that the majority of them will within the next few years be working or studying in the Metropolis, a significant proportion must shortly be exposed for the first time to direct attack by the tubercle bacillus. In view of the fact that it is no longer seriously disputed that B.C.G. vaccination confers a significant degree of protection against primary tuberculosis and its sequelae, the question presents itself whether such groups of young people should any longer be left unprotected against random tuberculous infection.

The argument against B.C.G. vaccination in this country rests largely on the hypothesis that conditions here may differ from those in Scandinavia, and that experience there cannot be held to apply in Britain until proved by a series of pilot surveys conducted over a period of years. Conditions it is true are different—there is a greater pool of infection in, for instance, London or Glasgow than in Oslo or Stockholm. For the tuberculin-negative group therefore, the position is worse, the risk of infection is higher and the argument in favour of B.C.G. vaccination correspondingly stronger, for does anyone seriously contend that if it is thought unsafe for young people to live and work in the Mantoux negative state in these two Scandinavian cities it can be anything otherwise in the conditions obtaining in most British cities?

It may be objected that in any event the majority of the inhabitants in really congested areas become Man

toux positive at an early age. But does anyone know what proportion is negative in any area of any city in the country? The truth is that we do not know at all accurately the level of tuberculinisation amongst our own population, and what we do know is far from reassuring. It is clear, for instance, that there is a large influx of tuberculin negative individuals into our great cities year by year—the steady immigration from Ireland and rural Scotland into Glasgow comes particularly to mind to supplement the example of the “great wen” itself. We know, too, that an increasing proportion even of those born and brought up in cities contrive to escape tuberculous infection till late adolescence, and that infection at this age is liable to have extremely serious consequences. What we do not know is the extent of the problem, city by city, area by area, age group by age group. Limited pilot surveys, including the one mentioned above, reveal only a small glimpse of a complex and varying situation, and the fact that some officially approved investigations are being conducted should not be allowed to obscure the necessity for large-scale surveys in every area. We have now reached the stage where it should be incumbent on every health authority to ascertain the level of tuberculinisation of the population under its care. There is no insuperable difficulty about this being done expeditiously in each major centre of population, in the survey quoted above the actual application of the tests on 495 girls was carried out in two hours by a team of six people (doctor, two nurses, two teachers, clerk). School leavers are the most obvious and probably the easiest group to start on, but clearly the factory population, the antenatal group, and others would require later investigation. The opportunity, too, should be taken to Mantoux test all Army recruits, for that matter, there would appear to be no good reason why the negative reactors should be denied BCG since experience of the vaccine even in this country is sufficient at least to indicate its safety.

We must, therefore, make a determined attempt to define the problem confronting us. In so doing we shall gain much valuable information regarding the epidemiology and natural history of tuberculous infection. When we know what proportion of our young people are at risk we shall be better able to estimate their danger and to consider the role of BCG in relation to existing facts. There are now upwards of 43,000 pulmonary tuberculosis notifications per annum in this country, with no noticeable trend towards reduction. A comprehensive effort on a national scale to reduce the figure is clearly indicated. We cannot afford to pay mere lip service to prevention when there is available a possible preventive measure which is safe, scientific, capable of wide application, and even cheap. In this connection the following report (not, be it noted, from Scandinavia) should give cause for reflection.

“A control program was inaugurated (in Japan) by the Supreme Command of the Allied Powers. As a part of that program, approximately 31,000,000 persons had received BCG immunisation up to May, 1949. The control program has resulted in a reduction in the mean annual death rate from 280 per 100,000 population in 1945 to 181 in 1948. Analysis of the deaths by age groups indicates that the entire reduction has occurred in the age groups immunised with BCG. The death rate in non immunised groups has not been appreciably reduced during this period. Within the immunised groups the mortality has been reduced by 88%.”

In view of this and other evidence accumulating in different parts of the world, can there be any advantage in delaying further a major investigation into the level of tuberculinisation of our own population?

Clare Hall Hospital, South Mims,
Hertfordshire

A G HOUNSLOW
N MACDONALD

VITAMIN B₁₂ IN PERNICIOUS ANÆMIA

SIR,—In your report (Sept 23) of the International Congress of Haematology I am quoted as saying that I now give “a minimum of 60µg [of vitamin B₁₂] weekly, increasing up to 200µg if there are neurological complications.” The truth is that for routine purposes, now that cheap vitamin B₁₂ concentrates are available, I usually give 60µg every three weeks, with more frequent and perhaps larger doses (rarely more than 100µg a week) for patients with subacute combined degeneration of the cord. This does not mean that smaller amounts would necessarily be inadequate. I have, in fact, some 40 or 50 patients who have been receiving much smaller maintenance doses—namely 10µg of vitamin B₁₂ or B₁₂ every two weeks. This is a special group in which the effects of vitamin B₁₂ and vitamin B₁₂ are being compared, these patients have little or no neurological involvement and attend frequently so that the dose can be increased at once should the need arise. Naturally one would not advise such low maintenance doses for routine use in patients not under close observation.

Royal Victoria Infirmary
Newcastle upon Tyne

C. C. UNGLEY

NO TOOLS

SIR,—Your leading article of Sept 23 has focused attention on the appalling inadequacies of some of the chest clinics in this country. As you point out, comparison with well established and well staffed clinics only underlines these deficiencies. The fact that some areas have been able to integrate a first class service is the result of satisfactory negotiations between chest physicians and their local boards. Many of course have inherited well organised dispensaries but several efficient clinics have had to start pretty well from scratch since the inception of the National Health Service.

It would appear that in many of the less satisfactory areas the lack of progress has been due, not to the absence of foresight or planning on the part of the chest physicians, but to the refusal of hospital and regional boards to allow more than token payments to the chest services. It is surprising how many members of regional and hospital boards, both lay and medical, have an erroneous impression of the requirements and the work of an efficient chest clinic. I feel that one of the best ways to get uniformity throughout the country would be for each regional board to appoint a tuberculosis subcommittee—many indeed have one already. These committees could meet centrally and decide on the basic requirements and personnel.

If the responsible authorities in backward areas will not take action to improve their services, they will eventually be forced to, by local agitation, with all the unpleasant publicity and recrimination that this would involve.

M R C P

SIR,—The letter from “M D” and your leading article of Sept 23 are daggers turning in the hearts of those of us (and we are many) who lack the tools, and whose thoughts are bitter and angry at what has been for years the great betrayal—the betrayal of the tuberculous and of those who minister to them.

Let it be noted that the Paddington and Kensington clinic was built by private enterprise, not by the municipalities it serves. The blame for the inefficiency and inadequacy of tools and buildings (and oh, what buildings and what sanitation!) must lie squarely on the shoulders of medical officers of health, public health committees, and the Ministry of Health, who for thirty years or more turned a blind eye to the desperate needs of this specialty. The new health service is in no wise to blame for the legacy it inherited—a monument to the

indifference, indolence, and parsimony of official medical and lay bureaucracies which spent money on this charge upon them on two counts only (1) pharisaically, to make clean the outside of the pot, (2) when 'dispensary' buildings had become so decrepit that they were in danger of being condemned by the local sanitary inspectors.

In some areas, however, staffs have succeeded in making bricks without straw. In the Folkestone area, without adequate hospital facilities, but thanks to a helpful and loyal staff and coöperative colleagues in general practice, we have been able to maintain a service of operative or chemotherapeutic treatment or both, without recourse to sanatorium or pulmonary hospital beds for the past six years. The results have amply repaid the heavy extra work involved.

Folkestone

B G EDELSTON
Chest Physician

SIR,—The readers of your leading article of Sept 23 might like to learn what can be accomplished where a regional hospital board has an adequate plan, and where a hospital management committee is prepared to coöperate wholeheartedly in putting this plan into operation.

A little less than a year ago the East Anglian Regional Hospital Board accepted a report outlining a scheme for a comprehensive chest service for the whole region. At that time in Ipswich and East Suffolk, an area roughly forty miles square there was no chest clinic. In one public health department two or sometimes three half-day sessions were held weekly at which old and new tuberculous patients were seen. Radiological and pathological investigations could be arranged at a nearby general hospital. For the rest of the area patients notified as suffering from tuberculosis were visited in their homes by the district medical officer of health.

So much for things as they were. During the past few months a brick built ward at the local isolation hospital has been adapted to serve as a central clinic. It is equipped to undertake all normal outpatient investigations and radiological examinations. Only patients requiring tomography have to visit one of three centres within a mile or two of the clinic. Five subclinics housed in small hospitals or in premises provided by the local health authority have been established at the main centres of population in the area. Each has an X ray machine adequate for standard radiography of the chest, and at some X ray screen examinations will be possible. All but one of these subclinics will be in operation this month. Each will be staffed from the main centre in Ipswich where there are one full time and one part time nurse one full time and one part-time radiographer a dark-room assistant and the necessary clerical staff. There are as yet no full time tuberculosis health visitors but arrangements have been made so that the local health authority health visitor is able to attend the clinic session at which known tuberculous patients from her area attend.

The physician has 80 hospital beds under his supervision. The nearby sanatorium closed during the late war because of shortage of nursing staff is being opened as and when modernisation and staffing permit. At the moment 60 beds are occupied, and it is hoped that there will eventually be 120. An almoner has been appointed to the 'chest service'. She attends to the needs of all patients whether they be inpatients or outpatients.

The local health authorities have at all times been very helpful and schemes are afoot to develop and extend the preventive and aftercare aspects of tuberculosis. Regular contact examinations have been started and among the first 200 examined 8 new cases of active tuberculosis were discovered. Although the main centre was opened only three months ago weekly attendance of patients now numbers 240 about one third of whom are referred for the first time for consultant opinion. The waiting list of patients requiring sanatorium treatment is short, but this is due only to careful selection of patients and to undertaking where possible, treatment in the home. Hostel accommodation for the ambulant and often homeless patient is urgently required, and if provided would free many hospital beds that are by comparison, expensive to maintain.

Although we have had our 'teething troubles,' and 'growing pains' obstruct the peaceful daily

routine, one can look back upon the last ten months with a feeling of satisfaction and renewed confidence in our belief that tuberculosis can be banished within a generation.

Ipswich.

CHARLES J STEWART

PUERPERAL URÆMIA DUE TO ACUTE UPPER-NEPHRON NEPHROSIS

SIR,—In answer to Dr Govan and Dr MacGillivray (July 22 and Sept 23) may I point out that the pathological effects of acute renal failure are manifest in the kidneys within about 8 hours of the initial cause? Whatever the causal mechanism and whatever the explanation, the now well known findings merely indicate the varying degrees of degeneration and necrosis in the cortex and medulla. Subsequent effects related to continued anoxia and superimposed overhydration will be apparent in those areas which have not succumbed to cortical necrosis but have not recovered, or are not recovering, by the 10th to 12th day. These areas are, in Govan and MacGillivray's article, localised around some of the cortical glomeruli. The title of their article suggests that these affected areas caused the uræmia. Records of two of their three cases, however, indicate that on the day of death at least 1000 ml of urine was passed, despite continued vomiting previously, and suggest that in the 24 hours before death something in the nature of 170 litres of fluid had filtered through the renal glomeruli and that nearly this same amount had been reabsorbed by undamaged or recovered nephrons. Thus it can hardly be maintained that all the proximal tubules were hydropic, but only those grossly affected by anoxia and unable to do the vital work of transferring the water back to the already diluted circulation.

It is feasible that were serial sections of such kidneys examined, in addition to completely normal nephrons, all degrees of degeneration and regeneration would be found affecting all parts of many nephrons, although in the first instance the main brunt of the damage seems to be borne by the distal convoluted tubules and hence these are the first to show signs of recovery.

In conclusion, I never did consider that overhydration, by itself, could produce lesions anywhere in the nephron, but, superimposed on anoxic and devitalised cells—whether they be in the liver, brain, or kidney—overhydration will surely lead to hydropic degeneration. As regards Govan and MacGillivray's suggestion that the distal parts of the nephron are responsible for water and salt exchange, I would point out that, in mammals at any rate, 80% of the water in the glomerular filtrate is reabsorbed in the proximal tubules, together with a proportion of the chloride.

Peterborough

D W BRACEY

THEORY OF BARBITURATE ACTION

SIR,—Velazquez and Elio² have advanced a general theory of narcotic action, which they suggest is due to the inhibition of acetylcholine synthesis. For the action of barbiturates the following explanation is proposed.

Barbituric acid consists essentially of a pyrimidine ring

This has little if any narcotic action, but suitable substitution of the H atom at the position R will confer

1 Wright S. Applied Physiology London 1945.

2 Velazquez L, Elio, F J, Brit chem Abstr, 1945, A III 636,

this property. The pyrimidine ring also occurs in the pyrimidine moiety of thiamine

Thiamine plays an essential part in the synthesis of acetylcholine: indeed it is actually produced with acetylcholine at the cut end of a peripheral nerve, more especially during stimulation of the nerve.³

By an extension of the Woods and Fildes theory of the action of sulphonamides by "selective inhibition," it seems likely that if a sufficient concentration of barbiturate should be present in the blood stream, the barbiturate would combine with certain constituents of the nerve cells and thus render them less capable of utilising thiamine in the synthesis of acetylcholine.⁴ As a result of the comparative lack of acetylcholine, the general activity of the brain would be depressed. This would explain its action in the case, for example, of epilepsy.

My thanks are due to Prof W. E. Jessop and Prof W. R. Fearon for their advice and encouragement.

Dublin

H. W. DALTON

INTRATHECAL TUBERCULIN

SIR,—Another possible explanation of the recovery of patients with tuberculous meningitis treated with intrathecal tuberculin (Dr Smith and Dr Vollum, Aug. 19) is that the local tissue reaction to tuberculin in these sensitised subjects released sufficient fibrinokinase to activate enough plasminogen to lyse the fibrin which was causing subarachnoid block. Ungar and Mist¹ reported that formation of fibrinolysin from its inactive precursor could be brought about by adding specific antigen to the serum of sensitised guinea-pigs. Dr Jackson (Sept. 16), in drawing attention to the meningeal irritation that may be caused both by streptomycin and by tuberculin, does not explain the dramatic recoveries of patients already showing hydrocephalus.

THREAT TO A SMALL GENERAL HOSPITAL

SIR,—Mr. Howkins in his letter of July 15 is quite right. The threat to the integrity of St. John's Hospital, Lewisham, is not an isolated example.

In one hospital with which I am acquainted, it was rumoured that the obstetrical department would be moved from the main hospital to another building altogether. This dismemberment of general hospitals, thus robbing them of the benefits of specialised departments, can only be a retrograde step, as Mr. Howkins says. Whilst, on the surface, it would appear that the isolation of specialised departments in separate self-contained hospitals is good planning, it encourages over specialisation. In the long run, this can only be detrimental to the patient, for it is the disease rather than the patient which becomes the object of treatment.

It is to be hoped that this dismemberment of general hospitals will not be proceeded with, for they are undoubtedly the mainstay of the hospital service.

In England Now

I WAS trying to compose a lucid letter to Sir Stafford Cripps the other day, when I chanced to look out of the window and saw a cat sitting on the lawn next door. He was obviously enjoying the sunshine and conducting a leisurely and dignified ablution, as behoves the sire of most of the kittens in this district. It is part of his routine to sit there each day (weather permitting) waiting for a rather boisterous and very exhausting Dalmatian puppy to be taken for a walk after tea. When the pup's unsophisticated yelps have vanished into the distance, the cat strolls indoors, inspects his saucer, and then settles down in our armchair to ruminate on mice and men before starting the serious part of his day's work. For about supper time (again weather permitting) he sets out to do a little procreanting, and if it is a warm night he may not return to our chair till dawn.

When the weather is fine, he spends his mornings and afternoons wandering round the neighbourhood, sharpens his claws on an old apple tree in the rector's garden, and takes a quiet snooze on a heap of grass cuttings. If he feels energetic he may stalk a few birds, he seldom catches any, but that does not matter, for the sport amuses him and there is always something in his saucer, if he feels a bit peckish.

When the weather is not all that he feels it ought to be, he stays indoors. There is usually a fire to sit by, or a radiator, and if the worst comes to the worst he can always lie down by the kitchen stove. When, as a result of this lack of exercise, his appetite wanes, the women of the house try to tempt him with cream and sardines or perhaps a morsel of chicken.

Though he is out a good deal, the cat has our chair to himself much more often than I do, and it is seldom that we share it. I have nearly 1000 cards in the filing cabinet in my surgery, and he reaps the benefit. He is the clever one, I am the mutt.

* * *

She was imaginative and polysymptomatic, and she complained a great deal of "fluttering and dancing" in the rectum. Diligent search failed to reveal any evidence of such terpsichorean activities, and the stools were reported as containing a normal flora. "It seems evident," wrote our psychiatrist, who finally got landed with her, "that there are fairies in the garden of her bottom."

* * *

While I was visiting the butcher, his wife bade one of her sharp Cockney sons go out to the chicken house in the field behind the shop and pick up the eggs. The boy grumbled, as boys will. "I don't wanna go," he muttered. "I'm afraid of the cows and the nettles sting me legs." "Go on with you," said his mother, and, always prepared to support parental authority, I added, "What sort of a man do you hope to be, Derek, if you're afraid of cows and nettles?" "A sailor," he replied. He had me there.

* * *

"Woman," wrote a Peripatetic recently, "is so practical but man, man is inspired." And how right he is! Take bed making, for instance. For how long do you suppose, have women made beds in the conventional manner, from below upwards? Anyone who has done it single handed will know that this involves perambulating around the bed several times, at any rate when dealing with the bilocular, or double bed, variety. Bed-making husbands, whose wives have taken the kids off to the seaside, should therefore note the following method. On rising in the morning the bedclothes are reflected medially instead of caudally, as is customary. After the bath and breakfast, the bed is closed in layers from within outwards, first down one lateral border and then, exerting traction, down the other. The inferior margin is dealt with on the return journey. Thus a minimum of peregrination is required. For less particular bachelors, I have even simpler advice: if the bed is left unmade until one returns home in the evening—well, there doesn't really seem to be much point in making it at all.

News

The awards committee under the chairmanship of Lord Moran have now selected about 1500 specialists who are to receive distinction awards. Their names will not be published. Most of the awards of £2500 and £1500 have now been decided but 400-500 further awards mostly of £500 will be made shortly. Those to dental consultants have still to be considered.

At the 21st anniversary dinner of the Royal College of Obstetricians and Gynaecologists held on Sept 29 Prof Hilda Lloyd the president announced that Sir Arthur Sims has endowed a Commonwealth travelling professorship and the Bernhard Baron Fund has given £10 000 for a travelling scholarship. These donations brought the appeal fund within sight of £100 000 and Professor Lloyd reminded her listeners that its other aims were to provide a larger home for the college preferably on a common site with the other Royal Colleges and to provide facilities for research. Sir John Anderson proposed The College and Mr C F Gibberd The Guests. Responding for the latter Dr Russell Brain F.R.C.I. suggested that their only common claim to the hospitality of the college was that they had all been born. They were grateful for the college's postnatal interest in them and for what he might call this follow up investigation.

Notifications of poliomyelitis in England and Wales during the week ended Sept 23 were paralytic 265 (201) non paralytic 151 (187) total 419 (478). The figures for the previous week are in parentheses. For the second successive week there has been a decided fall in notifications. Uncorrected notifications for this year now total 6023. The corresponding figures for 1947 1948 and 1949 were 6192 1361 and 3254.

WE must again express our regret at being unable to present various articles that need early publication. Not least in medical science, the blockage of normal channels of information can soon do real damage. Hence we welcome the greater sense of urgency lately shown by those charged with finding a solution of the present printing dispute.

Electrophrenic Respiration

A vast public is still fascinated by the ingenious "iron lung" devised in 1929 by DRINKER and SHAW¹ for "prolonged administration of artificial respiration". This apparatus is alternately the hope and the despair of the clinician called on to treat bulbar or bulbospinal poliomyelitis with respiratory failure. He can rarely prophesy whether the treatment will be (1) a brilliant success, tiding the patient over a difficult period until use of the respiratory muscles is restored to him; (2) a comparative failure with a hopelessly paralysed patient depending on the respirator for continued existence; or (3) a complete failure, giving little or no relief because of an obstructed airway or concomitant paralysis of the respiratory centre. Many of these cases are complicated by pharyngeal or laryngeal paralysis, and the consequent pooling of mucus leads to obstruction of the respiratory passages. Under these conditions the violent inspirations induced by the respirator give rise to a negative pressure in the bronchioles and alveoli, into which plasma and red cells are sucked, producing hæmorrhagic pulmonary oedema. To ward off this danger respirator treatment may be combined with postural drainage and suction, but this is not always effective, and of late years tracheotomy has often been employed as an additional measure, especially in the U.S.A., where experience of this type of poliomyelitis is vastly greater than elsewhere.

None of these methods suffices, however, when the patient begins to exhibit the grossly irregular "respiratory fibrillation" characteristic of severe damage to the respiratory centre. Here the spontaneous rhythm does not often conform with that of the respirator, and death usually follows fairly rapidly. Sometimes it is true, if the negative pressure of the respirator is increased to 30 cm. water the patient may be induced to cease all respiratory effort, but this step is taken at the risk of inducing alkalosis. A new and apparently effective method of meeting this difficulty is now described by a Boston team under the leadership of SARNOFF.² It has been shown in animals and man that electrical stimulation of one or both phrenic nerves will suppress spontaneous respiration and induce artificial respiration, and such stimulation, applied externally through an electrode over the motor point of the phrenic nerve, can be used to induce smooth, regular, rhythmic respiration, provided that at least one lobe of the diaphragm is working. Patients with irregular, shallow, spontaneous respiration who failed to adapt their breathing to the respirator's rhythm have been submitted to this stimulation for periods varying from eight hours to several days. It seems that, even after a few hours, spontaneous respiration may be greatly improved, but in the worst cases stimulation may have to be continued for some time before the respiratory centre has sufficiently

recovered. In one case the immediate effect was a change from ineffective shallow, irregular respiration to Cheyne-Stokes respiration, which proved to be an intermediate stage on the way to full recovery of the respiratory centre. SARNOFF and his colleagues describe 9 cases in which this method was applied apparently with conspicuous success. Most of them were grossly dyspnoeic, and the patients might otherwise have been expected to die. More experience will be needed before the value of this device can be established. The apparatus should not be used unless the operator has made himself proficient with it, and to become proficient he must practise on normal volunteers.

It is becoming evident that the somewhat haphazard methods by which we have tried to deal with these desperate cases are becoming obsolete. If poliomyelitis persists in this country on a serious scale, we shall have to build up specialised and well-equipped teams of doctors and nurses to deal with threatened or actual respiratory failure.

Annotations

SAFEGUARDING THE DOCTOR

THE latest report from the Medical Protection Society¹ describes many interesting cases, but as Sir Ernest Rock Carling said in his presidential address at the annual meeting last week, the society's most important work lies in dealing daily with requests for advice: it offers a preventive as well as a curative service. Under the N.H.S. doctors are more than ever in need of such protection for the Ministry of Health, as might be expected, assumes no responsibilities that can legally be placed on the clinician. Among other points Sir Ernest made the following: (1) To make sure that swabs are not left in the body every operating theatre must have a discipline: what the particular practice is does not matter so much as its regular observance. (2) Dental packs to prevent the swallowing of teeth should be large and preferably should have a tape attached. (3) When part of a needle remains in the tissues the doctor should not admit liability but should send the fragments (both if possible) to the society for metallurgical examination later if necessary. (4) Every hospital should have written rules making it clear on whom responsibility rests for giving anti-tetanus serum and newcomers to the hospital should ask what the rules are. (5) All doctors should take out a policy with an insurance company covering mishaps (such as falls) on their premises. Sir Ernest also referred to the vexed question of responsibility for work done by a registrar or other junior doctor at the request of a senior: when something goes amiss it is, he feels, a little hard that the onus should be entirely on the man working under instruction.

Mr W. M. Mollison, the treasurer, reported that the amount spent per member last year was £1 4s 7d, of which 14s 2d went in legal expenses and indemnities. The deficit of £2195 was covered however by an increase in the value of capital funds from about £112,000 to nearly £119,000, and the subscription to the society remains at £1¹.

CANCER OF THE MOUTH

DESPITE new methods of treatment the prospects of the patient with cancer of the mouth are not impressively better than they were half a century ago. Two of the reasons are made clear in an account of 800 cases observed by Ledlie and Harner² at the Royal Cancer Hospital, London. In the first place the patients were mostly well up in years, so that the natural expectation of life was short. Of the whole series,

HOSPITAL NON-MEDICAL VACANCY

Birmingham United Birmingham—Sr Hosp Physicist. (rad)

Notices of vacancies will appear in this form (without charge) until normal publication can be resumed

died of recurrent hæmorrhage, malformations of the kidney were found in 9 cases, including 5 of polycystic kidney, 1 of horseshoe kidney, 1 of double ureters, 1 of hydronephrosis associated with an accessory kidney and 1 of well marked foetal lobulation. Magee in 58 necropsies, found cystic kidney in 1 and horseshoe kidney in another.

The incidence of recurrent hæmorrhages and the prospects of return to normal health have also been studied. Hyland was able to trace 67 of the 91 survivors. Of these 67, 14 had died of recurrent hæmorrhage and 7 of intercurrent disease. For the remaining 46 the average time of follow up was ten years. Of this group, 26 were free of disability and able to live normal lives, some had had headaches and general fatigue for a year or two after leaving hospital but had gradually improved. A further 10 had mild disabilities, such as headache, mental dulling, or residual cranial nerve palsies, but were able to work. 4 had more severe defects—in 3, a hemiparesis—but were doing light work. Finally, 3 were unable to work, because of severe disabilities such as aphasia and hemianopia combined. Ash, Upmark and Ingvar recorded recurrent hæmorrhages in 10 men with 4 deaths and in 29 women with 19 deaths and state that the mortality in recurrent attacks was about twice as great as in initial attacks. Thus with 38 deaths from the original attack, 23 from a recurrent attack, and 13 from other causes there were 64 survivors. Of these half were able to carry on their normal occupations while the other half were more or less severely crippled. The follow up period varied being over ten years in 32 cases and five years or less in 41 cases.

These figures emphasise the serious outlook for patients who have had a subarachnoid hæmorrhage, but they also

show that there is a definite group who survive an initial attack and make a good recovery without further hæmorrhage. Such results as these will be of a particular value when comparable figures are obtained for patients treated surgically either during the initial hæmorrhage or, in an effort to prevent further disability after the bleeding has stopped. Meanwhile however, these accounts are a salutary corrective to the view that 'the over all mortality among patients with spontaneous hæmorrhage due to rupture of an aneurysm approached 100% with therapy available prior to the advent of surgical intervention.'¹⁰

Sir ERNEST GRAHAM LITTLE consulting physician to St Mary's Hospital, died on Oct 6. He sat as member of Parliament for London University from 1924 to 1950 and he was a member of the senate of the university for 44 years.

Air Vice Marshal Sir JOHN MCINTYRE, director of the R.A.F. medical service from 1930 to 1935 died on Oct 7 at the age of 70.

Lord HADEN GUEST has been elected president of the Association of Scientific Workers in succession to Lord Boyd Orr.

THE eight nations and territories in the W.H.O. region for South East Asia have increased their contributions to the organisation by 20% in an effort to avoid reductions in the health programme in the area owing to the budget cuts made at the last World Health Assembly in Geneva.

INTERNATIONAL CONGRESS OF PSYCHIATRY

THE 1st International Congress of Psychiatry held in Paris from Sept 18 to 27 under the presidency of Prof JEAN LHERMITTE and Prof JEAN DELAY, was well attended by representatives from England, Western Europe, and Latin America, but numbers from the United States fell below expectation. No Russian delegates were present.

SHOCK THERAPIES

Dr U CERLETTI (Rome) pointed out that the reactions evoked by electric shock vary widely as between different species but are relatively constant in the same species. Often they may be taken to represent primitive escape or defence reactions. He laid stress on the widespread somatic changes evoked by E.C.T., in particular those governed by the diencephalic vegetative centres and he sketched a working hypothesis to account for the beneficial effects of convulsion therapy in man.

Dr A. M. FIAMBERTI (Varese) described his method of intravenous injection of acetylcholine and produced some evidence of its superiority to E.C.T. in the treatment of schizophrenia.

Dr J. J. LÓPEZ IBOR (Madrid) held that E.C.T. is not indicated in every case of endogenous depression and that it may have value in the treatment of catatonic and certain forms of paranoid schizophrenia. Prof L. J. MEDUNA (Chicago) retracted his earlier opinion that E.C.T. is of value in genuine schizophrenia but believes that certain symptomatic schizophreniform syndromes (oneirophrenias) respond favourably to this treatment. These syndromes, Prof Meduna thinks, are associated with a wide variety of aetiological conditions but are characterised by a specific disturbance of carbohydrate metabolism. This he attributes to a partial inactivation of hexokinase due to overaction of the anterior pituitary hormone.

Hypoglycæmic shock treatment was discussed by its originator, Dr MANFRED SAKEL (New York), who emphasised the therapeutic importance of coma as opposed to convulsion in the insulin treatment of schizophrenia. The treatment he said, is still only a tool, whose effect "does not depend so much on the tool as upon the man who uses it."

LEUCOTOMY AND TOPECTOMY

The rationale of prefrontal leucotomy was explored by Dr BARAHONA FERNANDES (Lisbon). Leucotomy, he said, is apt to provoke an increase in general responsiveness associated with a certain blunting of social judgment. Intellectual changes are variable but seldom profound.

Prof WALTER FREEMAN (Washington) laid great emphasis on the plane of section in relation to the ultimate outcome of operation. In his experience, defects of social judgment are rare after the more anterior cuts, but this operation may fail in its purpose of symptomatic relief. With more posterior cuts, on the other hand, postoperative social defects may outweigh improvement of emotional symptoms. 'The important thing is to place the incision just far enough back in order to relieve the emotional disturbance without, at the same time trespassing on those parts of the brain that are requisite for adequate social adjustment.' In assessment Prof Freeman considers it more important to study what patients actually do with their intelligence than to measure what they can do on formal tests.

None the less, the effect of leucotomy on intellectual test performance was discussed by a number of contributors. Dr G. RYLANDER (Stockholm) reported a significant lowering in I.Q. on a number of tests following the standard operation but observed that the loss was considerably less after inferior cuts. He had been unable to demonstrate any intellectual changes on tests in 21 cases after undercutting.

A further instalment of anatomical lessons from prefrontal leucotomy was communicated by Prof ALFRED MEYER, who summarised his findings from 122 leucotomised brains of which 61 were from patients who survived more than five months after operation. His principal conclusion was that the quantitative correlation between degree of personality change and extent of prefrontal damage completely over shadows whatever tendency there may be to specific localisation within the prefrontal areas. He was unable to report any decisive information from anatomical studies bearing on the pathology of functional psychosis and he issued a stern warning against premature attempts to correlate clinical with neurophysiological data. 'Speculation is never more dangerous than when in the guise of the exact sciences.'

GENETICS IN PSYCHIATRY

Dr F. J. KALLMAN (New York) in a circulated report, adduced evidence—mainly from studies of twins—supporting the hypothesis of basically single factor types of inheritance with respect to schizophrenia and manic-depressive psychosis. Dr ELIOT SLATER broadly agreed as regards schizophrenia but argued that multifactorial inheritance is the more probable in manic depressive syndromes. On the other hand, Prof L. S. PENROSE, arguing by analogy with the genetics of intelligence, thought it most improbable that any major psychosis could be attributed to single factor inheritance. He also warned students of human genetics against forcing their material into simple and preconceived mendelian schemes.

In a review of the genetics of oligophrenia, Dr J. A. FRASER ROBERTS argued that the polygenic determination of the

545 were over the age of sixty, and not one was under thirty-five. Secondly, when the patients first reported, metastases were already evident in 59%, excluding those where the primary growth involved the lip. Here metastases were found in only 25%, and, since these patients reported no earlier than others, metastasis from this site is apparently slower. Among the whole 800 there were 30 (3.75%) in which a second primary developed, usually this was in the digestive tract, and most commonly between the lip and the cardiac sphincter of the stomach. The Wassermann reaction was investigated in rather over half the cases, and it proved positive in 16% of these. It was most commonly positive with cancer of the tongue (28%), less often with cancer of the buccal mucosa (20%), and rarely with cancer of the palate (3%) and alveoli (0.5%).

As to treatment, widely different methods had very similar results. When cases were grouped according to the site of the primary growth the average net survival rate was found to be surprisingly uniform at about 30% at three years, 20% at five years, and 10% at ten years. (Here "net" implies the inclusion of all cases treated except those untraced and those dead of intercurrent disease.) In most buccal and oropharyngeal sites teluradium proved more effective than X-ray therapy. It seems, however, that early cases of cancer of the lip respond best to X-ray therapy, where metastases had not already developed this provided a three-year net survival rate of 91%. With early cases of cancer of the anterior two-thirds of the tongue surgical treatment gave the best results (6 out of 7 surviving for three years), with cases in all stages treated surgically, by radium or X-rays, or by combined methods the net survival rate was 30% at three years, 20% at five years, and 14% at ten years. With primary lesions elsewhere in the mouth radium gave significantly better results than X-rays, but with lesions in the oropharynx X-ray therapy proved no less effective than radium.

MEDICAL MYCOLOGY

At the turn of the century, the classical and dominating work of Sabouraud on the dermatophytes fostered the impression that medical mycology was concerned solely with the ringworm fungi and obscured the remarkable developments in the study of systemic mycoses which were taking place in South America. Coccidioidomycosis, rhinosporidiosis, and chromoblastomycosis, which have all proved to be important and widespread diseases, were first described in Latin America, and a strong tradition of investigation in medical mycology has been maintained there. It was therefore appropriate that the first International Congress for Microbiology to devote a separate section to medical and veterinary mycology should have been the one held last August in Rio de Janeiro on the fiftieth anniversary of the foundation of the Instituto Oswaldo Cruz—a laboratory which has made big contributions to medical mycology.

At the four well-attended sessions of the new section more than forty papers were given by speakers of ten different nationalities, and despite linguistic difficulties the discussion was lively and well-informed. Naturally, South American speakers predominated and the emphasis was on diseases of local importance, such as South American blastomycosis. Many of the visitors had more to learn than to give and they were inclined to wonder whether thorough study might not show that mycotic diseases are no less prevalent elsewhere.

Though part of the present confusion in the nomenclature of fungi of medical importance is due to taxonomic uncertainties, much of it could be eliminated by international discussion and agreement. The 4th congress, held in Copenhagen in 1947, appointed a special committee on medical and veterinary mycopathology, and the latest congress confirmed this committee in office. At Rio the committee met and agreed to prepare a list of recommended names of fungus pathogens similar to the British list¹ but on a wider basis, to standardise the common names of mycotic diseases, to consider the standardisation of culture media, and to compile a list of the addresses of medical mycologists. The secretary of the international committee is Dr A. Cury, Instituto Oswaldo Cruz, Rio de Janeiro, Brazil, but anyone in Britain can obtain information about its activities from the secretary of the Medical Research Council's committee on medical mycology, 38, Old Queen Street, London, S.W.1.

STERILISING THE GUT

DURING the last decade the mortality from operations on the lower bowel has fallen steeply. At the Presbyterian Hospital, New York, it is now only 3%, compared with 15% ten years ago. This fall cannot be ascribed to any one new technique, but the administration of sulphonamides and antibiotics has played some part. Sulphaguanidine¹ and later succinylsulphathiazole² and phthalylsulphathiazole³ have been used in attempts to sterilise the gut before gastrointestinal surgery. These comparatively insoluble sulphonamides reduce the bulk of the stool and bring down the content of coliform organisms to less than 1000 per gramme. The sulphonamides, however, have certain disadvantages, including slow action, a narrow antibacterial range, and toxic side effects. The usefulness of penicillin, which is non-toxic, is limited by its extremely rapid absorption and by its destruction by penicillinase in the lumen of the gut. Moreover, coliform bacteria are relatively refractory to it. As an intestinal antiseptic, streptomycin has some advantages over both penicillin and the sulphonamides, since it remains in the lumen of the bowel in high concentration and is more active against coliform organisms, on the other hand, resistance may appear within a few days.

Pulaski and his colleagues⁴ have now shown that the activity of streptomycin may be enhanced, and resistance deferred, by the simultaneous administration of glycuronic lactone—the inner anhydride of glycuronic acid which detoxifies a number of drugs in the body (Aluminium pectinate had a similar but less pronounced effect). 'Polymyxin B,' an antibiotic derived from *Bacillus polymyxa*, proved as effective as streptomycin in suppressing coliform organisms, but proteus strains were resistant to it. Pulaski and his associates say that Aureomycin⁵ and chloramphenicol were not effective, but the dosage they employed may have been too low. Dearing and Heilman,⁶ who used slightly larger doses, report that aureomycin is the most effective of the substances they have tested.

The evidence that preoperative chemotherapy significantly reduces complications and morbidity is not yet, however, statistically satisfying. Most of the experimental work has been on animals, and some experienced surgeons claim that prophylactic chemotherapy is unjustified because of the fresh problems it creates.

PROGNOSIS OF SUBARACHNOID HÆMORRHAGE

THE increasing ingenuity of neurosurgeons in the treatment of intracranial aneurysms has focused attention on the prognosis for patients with subarachnoid hæmorrhage. At the Toronto General Hospital, Hyland⁷ has studied 191 cases admitted between 1928 and 1942. Altogether 100 (53%) died as a result of the attack that brought them to hospital. This is in line with earlier accounts. Thus Magee,⁸ in an analysis of Ministry of Pensions cases, recorded 52 deaths among 150 patients in initial attacks, and Hamby⁹ 44 deaths among 130. In the Canadian series, of the 100 who died, 26 had recurrent hæmorrhage while in hospital, usually within two weeks of the initial attack. Factors pointing to a poor prognosis were unconsciousness at the onset, pre-existing hypertension, signs suggesting intracerebral bleeding, and advanced age, of the 48 patients between the ages of sixty and eighty, 33 (69%) had fatal hæmorrhages. Necropsies on 55 of the cases brought to light ruptured aneurysm in 44, subtentorial angioma (which had been diagnosed during life) in 1, and cerebellar hæmangioma in 1, in 9 no bleeding point was discovered, but it was thought that the source of the hæmorrhage was a leaking aneurysm.

In Sweden, Ask Upmark and Ingvar⁹ have followed up 138 patients admitted to the university clinics at Lund and Uppsala. Of these, 38 (28.3%) died during the first attack, the average time of death being the ninth day after the hæmorrhage. The post-mortem findings are of interest in connection with the probable congenital basis of intracranial aneurysms. In 47 necropsies, presumably including some on patients who

He had been unable to demonstrate any intellectual changes on tests in 21 cases after undercutting.

A further instalment of anatomical lessons from prefrontal leucotomy was communicated by Prof ALFRED MEYER, who summarised his findings from 122 leucotomised brains of which 61 were from patients who survived more than five months after operation. His principal conclusion was that the quantitative correlation between degree of personality change and extent of prefrontal damage completely over shadows whatever tendency there may be to specific localisation within the prefrontal areas. He was unable to report any decisive information from anatomical studies bearing on the pathology of functional psychosis, and he issued a stern warning against premature attempts to correlate clinical with neurophysiological data. Speculation is never more dangerous than when in the guise of the exact sciences.

GENETICS IN PSYCHIATRY

Dr F. J. KALLMAN (New York) in a circulated report, adduced evidence—mainly from studies of twins—supporting the hypothesis of basically single factor types of inheritance with respect to schizophrenia and manic-depressive psychosis. Dr ELIOT SLATER broadly agreed as regards schizophrenia but argued that multifactorial inheritance is the more probable in manic depressive syndromes. On the other hand, Prof L. S. PENROSE arguing by analogy with the genetics of intelligence thought it most improbable that any major psychosis could be attributed to single factor inheritance. He also warned students of human genetics against forcing their material into simple and preconceived mendelian schemes.

In a review of the genetics of oligophrenia Dr J. A. FRASER ROBERTS argued that the polygenic determination of the

innate component of high grade defect is demonstrated both by the close fit of the Gaussian curve to the level indicated and by the degrees of resemblance between high grade defectives and their relatives. But he agreed with Prof Penrose in ascribing inborn low grade defect to single major genes or chromosome abnormalities. He held that, for distinguishing between these two broad classes of endogenous mental defect, the psychometric method is at present the most useful tool.

Dr ELIOT SLATER reviewed in various communications important evidence bearing on constitutional predisposition to psychoneurotic illness and its relation to environmental stress.

TRENDS IN PSYCHO ANALYSIS

Dr F ALEXANDER (Chicago) advocated a method of analytical procedure somewhat more active than the classical Freudian method. He stressed the dangers of overdependence on the physician which are liable to result from rigid adherence to the orthodox method and the need for assisting the patient actively to adjust to his current milieu. Recent theoretical developments in psycho analysis were reviewed by Miss ANNA FREUD, with special reference to the problem of aggression. She also advocated well-designed sociological studies—e.g. of displaced children—to provide experimental checks on psycho analytic theory. Dr M LEVINE (Cincinnati) commented on the progressive integration of psycho analysis with psychiatry and general medicine which he believes to be taking place in the United States.

A general impression left by this symposium was that psycho analysis is now passing into a conservative phase with little prospect of fresh theoretical advance.

MENTAL TESTS

The place of mental tests in clinical psychiatry was forcibly discussed and tended to evoke extreme attitudes. In an admirably balanced communication, Dr MANFRED BLEULER (Zurich) urged that "projection methods" (e.g., the Rorschach test) have great value in displaying clinical syndromes already known but can contribute nothing new to psycho pathology. Dr D RAPAPORT (Stockbridge, U.S.A.) on the other hand, argued in a circulated abstract that diagnostic testing procedures should be more closely integrated with psychiatric theory. Dr P PICHOT (Paris) showed himself more closely in sympathy with the psychometric approach than is usual among clinicians and was much opposed to the empirical methods of test-validation in current use. He favoured a somewhat stricter rationale of test construction based on the methods of factorial analysis.

SOME OTHER TOPICS

Psychopathology of Delusions—This symposium provided evidence of a rapprochement between the organic and functional approaches to psychotic thought disorders. Dr G E MORSELLI (Novara) drew parallels between delusions in primary psychoses and kindred phenomena observed in anosognosia, depersonalisation, and mesaline intoxication. Dr P. GUIRAUD (Paris) attempted to relate delusional thinking to derangements at the diencephalic level depending either on structural lesion or emotional disturbance. Dr W. MAYER GROSS, in a general discussion of paranoid states strongly advocated their inclusion in the category of schizophrenias. "Paranoia," he maintained, "remains an idealised picture never reached in clinical reality."

Experimental Neuroses—Prof R W RUSSELL outlined the main methods of inducing experimental neuroses in animals and advocated the comparative approach to many problems in human psychopathology. A Pavlovian interpretation of traumatic neurosis was offered by Dr H J SHORVON.

Electro-encephalography—Dr DENIS HILL suggested that E.E.G. research is of theoretical rather than practical importance in present-day psychiatry. He discussed disturbances in thalamocortical relations as reflected in the E.E.G. and examined their relevance to behaviour. He considered also some problems arising from the special nature of the E.E.G. in catatonic schizophrenias.

Experimental Catatonia—Dr H DE JONG (Los Angeles), reviewing a long series of bulbocapnine experiments, concluded that experimental catatonia is a general form of reaction of the CNS. Though it has no specific etiology, its threshold

seems to be lowered in certain conditions in which there is a disturbance of liver function.

Six volumes of proceedings of the plenary sessions (published by Hermann & Cie, Paris) are available. It is hoped that abstracts of discussions and symposia will be printed later.

SENIOR HOSPITAL MEDICAL OFFICERS

AFTER discussion with professional bodies the Ministry of Health announce (S.H.B. [50]96) agreement that the following posts may suitably be filled by S.H.M.O.s:

Blood transfusion

Posts below that of director of regional blood transfusion service

Diseases of the Chest

Posts in a restricted part of this field (e.g., limited to routine tuberculosis dispensary work), medical officers of sanatoria either in charge of small units or below the rank of superintendent in charge assistants to a consultant in charge.

Gynaecology

Posts below the rank of head of a large department, and other posts where the scope for investigation and active treatment or the clinical responsibility is insufficient to justify consultant status.

Infectious diseases

Medical superintendents of small hospitals, at other hospitals posts below that rank.

Obstetrics (practised alone)

Posts at antenatal and postnatal clinics, posts in maternity departments which are under the general supervision of a consultant.

Ophthalmology

Posts primarily concerned with non-operative work—e.g. refraction.

Orthopaedics

Posts primarily concerned with non-operative work.

Pediatrics

Posts at welfare centres and other posts primarily concerned with child welfare.

Physical medicine, Venereal diseases

Post of officer in charge of a small clinic in large departments posts other than head of the department.

Psychiatry and mental deficiency

Posts of medical superintendent of small institutions (at larger mental institutions some posts below that rank), posts primarily concerned with limited fields of psychiatry.

Hospital establishments should include an adequate complement of widely experienced *anaesthetists* of consultant status. Some hospitals will also often need assistant *anaesthetists* of S.H.M.O. grade. The staff of a *pathological department* should consist of consultants and trainees, with a limited field for the appointment of assistant pathologists paid on the S.H.M.O. scale. The complement of consultants must depend on the size of the department, but where there are separate sections each in the charge of a pathologist under the general control of the head of the department—e.g., morbid anatomy, biochemistry, haematology, bacteriology, blood transfusion—each should be of consultant status. The establishment of *radiodiagnostic* or *radiotherapeutic departments* should include at least one practitioner of consultant status with trainees. Where this complement is not sufficient to deal with the work, it may be necessary to appoint assistant radiologists of narrower training and with more limited responsibility than the consultant, paid on the S.H.M.O. scale.

The establishments of departments of *general medicine*, *general surgery*—including urology and proctology—*obstetrics* and *gynaecology* (practised together), *cardiology*, *dermatology*, *otolaryngology*, *neurology*, *neurosurgery*, and *plastic and thoracic surgery* should not include S.H.M.O. posts.

The Ministry has asked regional hospital boards to revise their establishments in accordance with the above principles. This revision, however, will not affect the personal status of a doctor whose post may be regraded. Thus the S.H.M.O. whose post is regraded as consultant and the consultant whose post is regraded as suitable for an S.H.M.O., will both retain their present personal status. When a post which has been regraded becomes vacant it will be advertised according to its new status. When there is no suitable applicant of consultant status a consultant post may no longer be offered to one of the applicants as an S.H.M.O. post.¹ If the field of consultant applicants cannot be widened by a rearrangement of the duties of the appointment, it will be re-advertised as an S.H.M.O. post.

The Ministry also asks boards not to overlook the possibility that some part-time S.H.M.O. appointments—i.e., assistant anaesthetists, assistant geriatricians, assistant-pediatricians, or M.O.s in charge of small infectious disease hospitals—may appropriately be filled by general practitioners.

From Letters to the Editor

Methonium Compounds in Hypertension—In reference to the articles by Dr Turner and Dr Saville (Sept 2), I should like to refer briefly to our experience here.

Dr Restall and I have lately reported (*N Z med J* 1950 49, 206) some results which we regarded as hopeful and further work has been undertaken with Dr K. S. Alstad. The effect of methonium halides has now been studied in 80 patients with substantial hypertension and 26 patients with hypertension of the more severe types, including 9 with malignant hypertension, have been treated for one to nine months. Our general impression is that the methonium salts provide the most generally applicable method of controlling the blood pressure (B.P.) level (where this is desirable) in various forms of arterial hypertension. The cases studied include some of labile and fixed types of essential hypertension, essential hypertension with persisting or recurring high B.P. after sympathectomy, malignant hypertension, hypertension from chronic nephritis, renal insufficiency in hydronephrosis, renal tuberculosis, the acute phase of pregnancy toxæmia and hypertension following pregnancy toxæmia. In all cases the B.P. could be reduced—in all but 2 substantially. In many instances falls of 60–120 mm Hg in the systolic pressure and of 15–50 mm Hg in the diastolic pressure were observed.

In conformity with suggestions as to the pathogenesis of essential hypertension (*Brit med J* 1949 1, 791), we have worked on the principle that effective control over the B.P. level is essential in treatment. High B.P. is not to be regarded as merely symptomatic but as the means whereby multiple underlying pathological factors lead to the disabilities characteristic of the disorder. Our objective, therefore, has been to reduce B.P. as much as seemed safe and practicable. In order to do this we took advantage of the postural fall of B.P., patients slept in cardiac beds with the body inclined at 45° and the legs slightly lowered. Thus we needed comparatively small doses and have had few side actions. As far as possible we aimed at having the average systolic level below 160 mm Hg. As soon as patients were ambulant they were encouraged to sit upright and to stand.

Another advantage of having the patient propped up during the action of the drug is that if the B.P. falls excessively symptoms can be relieved within a few minutes by the patient lying flat. If much larger initial doses (e.g., 100 mg) are employed so as to reduce the B.P. when the patient is horizontal, there is a smaller margin of safety and parasympathetic effects are prominent. In the interest of safety I think that in hypertensives the initial dose of the halide, given subcutaneously or intramuscularly with the patient in the sitting posture, should not exceed 15 mg. Even with this small dose the systolic B.P. may fall to 90 mm Hg but when the patient lies down the pressure rises promptly to say 150 mm. At first, subcutaneous injections of 15–25 mg may be given twice or three daily. Patients almost invariably acquire tolerance to the drug, and the dose has to be increased considerably in order to maintain B.P. reduction. Eventually the subcutaneous dose may be stabilised at 50–250 mg twice or three daily.

These drugs can be used with no more danger than other powerful agents provided their effect is carefully observed particularly in the early stages of treatment. Standard dosage is unsatisfactory for an amount which would be ineffective in one patient would be dangerous in another. Effective doses should be approached over a period of several days. A salt-poor diet greatly enhances the effects of methonium halides.

When the B.P. has been reduced in this way for a large part of the twenty-four hours subjective and objective benefits have resulted. In 8 cases of malignant hypertension with papilloedema the following results were obtained: in 4 the papilloedema disappeared, in 3 it greatly diminished and the physiological cups reappeared, and the sole remaining evidence of papilloedema was an appearance suggesting oedema of a part of the disc margin. The remaining patient, who commenced treatment recently, shows unmistakable improvement but papilloedema is still present. One of these patients had a recurrence of papilloedema while under treatment but is now showing improvement again. In all grade III hypertensives so far treated haemorrhages, retinal oedema and soft exudates have either decreased considerably or disappeared. In all cases headaches have disappeared or greatly diminished. There has been reduction of such symptoms as breathlessness on exertion and dizzy attacks, and such manifestations as gallop rhythm and alternation of the pulse have disappeared

or diminished considerably. In a few instances there has been slight diminution of heart size and slight return of the electrocardiographic picture towards normal.

These changes are not due exclusively to the use of pentamethonium and hexamethonium. Pest in hospital may lead to considerable subjective and some objective improvement. The number of patients studied is small but the notable clinical improvement, associated with effective lowering of the B.P. is of a degree seen in a smaller proportion of patients treated by other methods.

So far we have regarded recent cerebral or coronary thromboses as contra-indicating methonium treatment, but in a tentative and exploratory way we have treated a few hypertensives with angina of effort. Our experience is limited to nine months and unforeseen difficulties may emerge but the preliminary investigations suggest that it is now unwise to submit any patient to the risk, trauma, and uncertain benefit of sympathectomy until there has been a trial for several months of effective B.P. reduction using methonium halides and taking advantage of the effect of posture. In some cases the combined effect of a salt-poor diet (0.2 g sodium) and pentamethonium or hexamethonium seems particularly favourable.—Prof F. H. SMITH, F.R.C.P. (Department of Medicine, Medical School, Dunedin, New Zealand.)

No Tools—Your leading article of Sept. 23 may leave the impression that better staffing and equipment of chest clinics, with the chest physician doing an increasing amount of domiciliary treatment is the most urgent need of the tuberculosis service. I submit that the most urgent problem which has been the same for twenty years is shortage of beds and of nurses. At this hospital five chest clinics, serving a population of 400,000, are accommodated in the outpatient department. The chest physicians attached to these clinics have a tuberculosis block of 56 beds together with a small number of beds in the general wards for the investigation of non-tuberculous pulmonary disease. Facilities for minor thoracic surgical procedures have existed since 1943 and since 1947 a full major thoracic surgical service has been operated. Active domiciliary treatment has been carried on by the chest physicians since the clinics were opened and experience has led to the conclusion that this method is no reliable substitute for hospital and sanatorium treatment. Streptomycin P.A.S. and for that matter pneumopertoneum and phrenic crush cure few patients but they give time for planning the appropriate attack on the disease. Any measure carried out in the home can be better carried out in an institutional bed and more beds are obviously needed. But I think that despite your optimism the Minister's request to hospital boards will not improve matters much. We cannot be satisfied until a patient with recoverable pulmonary tuberculosis can be admitted into hospital within a week of diagnosis and does not return home until his disease is controlled and non-infectious.—H. F. HAWWOOD, M.R.C.P. (chest physician St Helier Hospital, Carshalton Surrey.)

First International Congress of Internal Medicine.—This congress reported in your issue of Sept. 23 embodies the conception of internal medicine as a leading specialty in contemporary medical practice. It was right to hold this first congress in Paris, because that great school has always opposed itself to the splitting of internal medicine and it was right to select London for the second congress because British physicians showed the importance of the neurochemical integration of the organism and gave the death blow to Virchow's cellular theory.

According to present-day ideas internal medicine is "all or none." This does not mean that the narrow medical specialties are to be rejected but that their position has to be re-assessed. Plato's dictum comes again to the fore: "Good physicians apply their treatment to the whole body and attempt to treat the sick part or organ by treating the whole individual." This means that, say a cardiologist or gastro-enterologist must assess the whole individual above all, although he may apply his special techniques to a local manifestation. Thus cardiology, gastro-enterology, endocrinology, and even neurology or dermatology can no longer be considered as specialties in their own right but as subspecialties of internal medicine which the great American clinician, Dr Costa, characterised as the greatest of all specialties. We should not speak of cardiologists or gastro-enterologists but of internist cardiologists and internist gastro-enterologists, and special diplomas—at all events in medical branches—should

be awarded only to those who already hold a postgraduate qualification in internal medicine of the M.R.C.P. type

Will the congress succeed in fostering this new spirit? Those who took part in the Paris congress were mostly from the countries of Græco-Latin culture, including England, Latin Canada, and Latin America, and also Scandinavia. North America was scarcely represented, Germany not at all. Are we going to split into those who are animated by a comprehensive and humanistic intellect of the Græco-Latin culture and those who are obnubilated by the power of technique and machine? The London congress will have a tremendous significance from this point of view.—A. P. CAVADIAS, M.R.C.P. (London, W.1)

Kernicterus—In your issue of July 1, Dr Gerard speaks later on the possibility that kernicterus may be caused by hypoglycaemia. I have had the same thought, and have found it easy to produce kernicterus in rats by insulin shock combined with intravenous injection of bilirubin. However, I cannot confirm the presence of hypoglycaemia in infants who develop kernicterus.—RICHARD L. DAX, M.D. (Department of Pediatrics, College of Physicians and Surgeons, New York)

Treatment of Myasthenia Gravis—Your leading article of Aug. 19 takes a distinctly unfavourable view of thymectomy for the treatment of this disease. You apparently suggest that results would best be judged by electromyography, but this method, though of undoubted value in the diagnosis of some disorders, can only be used to record the electrical activity of a small number of muscles at any one time, and it is very difficult to take records from the ocular, bulbar, and other muscles commonly involved in myasthenia. Over a long term the best guide is surely the patient's general activities as compared with before operation: this method was adopted by Keynes in following up his patients.

Some patients do improve notably in the first two to three weeks after operation, but in the majority who benefit from operation improvement is slow and steadily progressive over many months. This slow improvement does not seem to me to be in any way incompatible with the operation being the cause of it. Unfortunately at present we are unable to tell which patients are likely to benefit from thymectomy, but Keynes's follow up, carried out in association with more than one physician, shows that of the patients without thymic tumours 32.5% were completely relieved of symptoms while another 33.3% had only minimal symptoms, and in my view the most significant fact is that there has been no relapse of myasthenic symptoms in any of these patients during follow up periods of six months to eight years.

Thymectomy is certainly not the final answer to the treatment of patients without thymic tumours, but from my experience of following up some 65 of the patients on whom Mr Keynes has operated I have no doubt of the benefit in about 60% of cases.—J. W. ALDRIN TURNER, F.R.C.P. (St Bartholomew's Hospital)

In England Now

THE man who is thinking of going to New Zealand was discussing seasickness at our sherry party. His own doctor had recommended a well-known proprietary remedy, but a doctor friend had told him that this would make his heart go to pieces. He looked miserably in my direction. I suggested 'Draminine,' but he said it was difficult to get. "Well," I asked reasonably, "why take any drugs at all?" And I told him how when I go for a long sea voyage I lie on my back until I am used to the motion—about two days, as a rule—and then all is well. He still looked dissatisfied. "My friend advises covering one eye," he mumbled, "and plugging both ears as well." The female guests around twittered that this would be very awkward. "Cover one eye and plug the opposite ear," I suggested. He brightened a little at that and said he would buy an eye shade. Then someone thought of Nelson who was notoriously subject to seasickness. I inquired whether this tendency had persisted after he lost his eye, but no one knew, and we parted vowing to make it a subject for research. Are one-eyed people seasick?

I resent the printing dispute. THE LANCET is now too light to wake me by falling from the letterbox on to the mat.

News

In England and Wales notifications of poliomyelitis in the week ended Sept. 30 were paralytic 222 (208), non-paralytic 109 (101), total 331 (310). Figures for the previous week are in parentheses. Uncorrected notifications for this year total 6761. The corresponding figures for 1947, 1948, and 1949, were 6665, 1140, and 3611.

On Tuesday Oct. 17, at 5 p.m. at St. Mary's Hospital Medical School, London W.2, Prof. U. S. von Euler of the Physiological Institute, Stockholm, will give a lecture on Hormones of the Sympathetic Nervous System and the Adrenal Medulla.

Dr I. M. R. Walsh, M.R.S., is to give the Schorstein lecture at the London Hospital, E.1 on Thursday, Oct. 19, at 11.15 a.m. He is to speak on Clinical Medicine.

At a meeting of the Society of Medical Officers of Health on Thursday, Oct. 19, at 5.30 p.m. at B.M.A. House, London W.C.1, Dr J. M. Gibson, M.O.H. for Huddersfield, will deliver his presidential address, entitled Give Us the Tools.

The Minister of Education has appointed a committee to inquire into medical, educational, and social problems relating to malnourished children. The members include Dr J. F. A. Underwood (chairman), Dr A. I. Alford, Dr Mildred Crank, Dr H. M. Cohen, Dr Wilfrid Sheldon, Dr W. Rees Thomas, and Dr A. Torrie.

The first meeting of the West Midlands Physicians Association will be held in Birmingham on Oct. 21. Further particulars may be had from Dr A. G. W. Whitfield, Queen Elizabeth Hospital, Birmingham, 15.

Dr Charles Hill is to preside over the fourth general assembly of the World Medical Association, opening in New York on Oct. 18. B.U.P. reports that the medical organisations of 39 countries will be represented.

Dr H. Balme has been appointed by W.H.O. and the U.N. department of social affairs as their consultant adviser to U.N.I.C.E.F. on the rehabilitation of crippled children in European countries.

A conference on the Physical Care of Books is to be held at the headquarters of the Library Association, Chancery House, Malet Place, London W.C.1 on Wednesday, Oct. 18, at 6.30 p.m., when Dr R. L. O. Williams is to speak on the Spread of Infection by Books.

At Oxford University freshmen are being invited to submit to mass radiographic examination.

The honorary fellowship of the Royal College of Obstetricians and Gynaecologists has been conferred on Dr G. W. Kosmak, editor of the *American Journal of Obstetrics and Gynecology*. Mr Geoffrey Keynes and Dr R. J. Minnitt have been elected to the fellowship under the rule permitting the election of practitioners who are not obstetricians or gynaecologists but who have made contributions to the specialty.

The unit for 14 premature babies mentioned in our issue of Aug. 19 (p. 312) was opened at University College Hospital on Oct. 1. Babies under 5 lb. who need special care can be admitted to the unit by arrangement with the children's house physician (Euston 5550).

The Treasury has sanctioned the purchase of 17 acres at Northwick Park, near Harrow, for the site of the new Charing Cross Hospital. The new hospital is to have 800 beds, an outpatient department, and medical school. It is not known when building will start.

In a letter to Mr David Ross Evans, whose treatment of cancer has been publicised by *Picture Post* (see *Lancet* Sept. 16, p. 176), the Minister of Health says that he has asked Sir Robert Robinson, M.R.S., Sir Alexander Fleming, M.R.S., Sir Ernest Rock, C.B., M.R.S., and Prof. H. P. Himsworth, M.R.C.P., to act as an independent committee to consider your claims and to advise whether they warrant further investigation and if so the way in which any investigation should proceed. In making this offer to Mr Evans he adds: "I must ask that you on your part will agree to abide by any decision which they may reach and furthermore, that you will be prepared to submit to the committee should they require it, full details of your materials and methods and will no longer insist that these can be disclosed only during the actual treatment of patients." Mr Evans has agreed to submit to the committee "the fullest records I can of past cases and whatever they may ask concerning my materials and methods." He believes, however, that his work "can never be fully and finally tested unless actual treatment of patients forms part of the investigation."

Corrigendum *Hazards of the Tyed Hip*—In our leading article of Sept. 30 the American estimate of the expectation of life for women of 60 should have been given as 5 years (not 5 times) greater than that of a man of the same age.

Births, Marriages, and Deaths

BIRTHS

FOX—On Sept. 16, in London the wife of Dr P. B. Fox, a daughter, GWYNETH WILLIAMS—On Oct. 5 in Denbigh, the wife of Dr T. Gwyneth Williams—a son.
HILLINGWORTH—On Oct. 1 to Dr Cynthia Hillingworth, M.R.C.P. (nee Redhead) wife of Prof. R. S. Hillingworth, M.R.C.P.—a son.
MACPHERSON—On Sept. 11, in London to Dr Margaret Macpherson (née Hutchinson) wife of Dr D. S. Macpherson—a daughter.
MATTHEWS—On Sept. 12 at Guildford the wife of Dr H. W. Matthews—a daughter.
SCHRYVER—On Sept. 26 at Ipswich to Dr Nancy Richardson Schryver—On Sept. 26 at Ipswich to Dr Peter Schryver—a son.

MARRIAGES

WATTS—Young—On Sept. 30 at Potts Wood, Kent Arthur Ernest Wall F.R.C.S. to Eva Margaret Young.

Dr HENCH's Visit

Dr PHILIP HENCH had to wait seven years—from 1941 to 1948—to vindicate his conviction that there exists in nature an antirheumatic substance "X". In the last fortnight he has been in Britain, telling eager audiences of the swift march of events since he and his colleagues discovered the effect of 'Cortisone' on rheumatoid arthritis. Elsewhere we print in summary one of his lectures. In this, and in his address to the Royal Society of Medicine on Oct 10, he made it clear that hitherto he has used neither cortisone nor adrenocorticotrophic hormone (ACTH) in routine treatment. Their effects, he insisted, are transient. In acute rheumatic fever, for example, premature withdrawal of the drug may be followed by relapse up to the time when the active stage comes to its natural end. The value of these hormones is likely to be greatest in the self-limiting diseases—notably rheumatic fever—and in some other disorders where, by tiding the patient over a crisis, they may save his life. At the Mayo Clinic cortisone has been found to control inflammatory conditions of the eye, particularly those associated with rheumatic disease, and at the Royal Society of Medicine Dr HENCH reported that remarkable reduction of symptoms and signs had been observed in uveitis, iritis, and iridocyclitis. In a case of uveitis advantage has been taken of this temporary abatement to operate for concurrent glaucoma.¹

One surprising development is the discovery that cortisone seems to be effective when given by mouth in doses comparable to those injected parenterally, and trials of oral administration are proceeding at the Mayo Clinic. Growing experience is also bringing growing knowledge of dosage and side-effects. In general, abrupt termination of cortisone treatment is to be abjured; otherwise in rheumatoid arthritis a "rebound" relapse may be evoked. This can be averted by gradually tapering off the dosage or by replacing, towards the end of treatment, cortisone (which inhibits adrenocortical activity) by ACTH (which stimulates such activity). Among the side-effects singled out by Dr HENCH for special mention are retention of fluid, impaired carbohydrate tolerance, major changes in the psyche, and spontaneous fractures. When side-effects are troublesome, either hormone might, he suggested, be best given in smaller doses than those which would restore the blood sedimentation rate to normal or even completely suppress the symptoms.

These substances act, not against the "pathological anatomy," but against the "pathological physiology," so the earlier they are given the better. In diseases where they are effective, they provide susceptible tissues with a 'seal like buffer' against the attacking irritant. "They do not put out the fire," Dr HENCH declared. "They do not act like a carpenter who repairs the damage after the fire. But they do provide an asbestos suit." How they act is still unknown, but this much is clear. "We must learn how to co-operate with, rather than dominate and supplant, the pituitary-adrenocortical mechanisms."

Annotations

GENERAL PRACTICE AND THE R S M

ON Nov 22 the Royal Society of Medicine is to launch an enterprise of unusual interest: its section of general practice will meet for the first time. Those who petitioned for this new section suggested that its objects should be (1) to narrow the widening gulf between specialist and practitioner, (2) to provide for the general practitioner "an active link with currently accepted ideas", and (3) "to keep alive the academic or scientific attitude to medicine and its allied branches which is so readily lost in general practice."

General practice, as its name implies, is not a special branch of medicine but a compounding of all branches, which may be shaped by the practitioner according to his resources and the needs of the patient at home or at work. This is partly acknowledged by the sponsors in their proposal that the section should "provide a focal point for correlating the work of all existing sections." In this respect, therefore, it would not constitute a further subdivision but rather a central link between them all. Whether this link will help or hurt the practitioner will depend on the way in which it is forged, for if speakers from other sections feel impelled to simplify their remarks, they will strengthen the damaging argument of those who would have it that medicine is of two sorts—the one rational, as practised by the specialist in hospital, and the other homespun by the practitioner in the surgery and home. Over quality, therefore, the section should brook no compromise. Where it might well work for compromise is at the meeting points—which now too often are the friction points—between the two groups. Whole sessions could profitably be devoted to the clinical notes which pass between practitioner and specialist, to the relation between the practitioners and the radiologist's and clinical pathologist's work, and to the division of responsibility between hospital and general practice in such disorders as epilepsy, peptic ulcer, and the disabilities of old age. In these discussions each side would at least gain a better grip of the other's circumstances. Indeed, the society's bold lead will have been rewarded if the section achieves only its first aim, by cutting into the mountain of misapprehension which divides the doctor within the hospital from his colleague without.

PLIGHT OF THE TUBERCULOUS

THE B.M.A. Representative Body last month expressed unanimous concern "at the present inadequacy of the measures to deal with the growing problem of tuberculosis." During the meeting Dr C O Stallybrass pointed out that the number of tuberculosis patients awaiting inpatient treatment has grown from 3000 to over 11 000. They may now have to wait anything from three to nine months for a bed, and, if they need thoracic surgery up to eighteen months. In his view the crisis is due, first, to shortage of nurses. The nurses should be paid adequately and, if they will not work in the country, should be put near towns. No added risk is attached to nursing in sanatoria: the risk arises mainly from the undiagnosed cases in general hospitals. Dr Stallybrass ascribed the shortage of beds also to the lengthening of the average patient's stay in hospital, because of improved methods of treatment and to the increase in notifications, especially in Scotland, which is partly a result of better diagnosis, many of the newly recognised cases are in old people. With over emphasis on ascertainment and under emphasis on treatment, he said, the service is getting out of step. The country has 13 beds for tuberculosis per 1000 deaths, but this is not enough, some countries have two or three times as many, in proportion to deaths. Sanatoria should have not waiting lists but waiting beds. Dr Stallybrass also urged that the preventive work is inadequate and the application of BCG vaccination incomplete. This form of immunisation could probably reduce morbidity to a fifth

¹ See Henderson J W *Proc Mayo Clin* 1950 25 490 and *Lancet* Sept 23 1950 p 406

and mortality to a seventh among those receiving it, compared with controls. For this work the ratio of tuberculosis officer hours to population must be raised, in Copenhagen the ratio is three times what it is in Britain. Despite improved means of prevention and cure, we still lack a co-ordinated scheme for this country, and "we cannot do it on the cheap". Dr D. S. Robertson contended that almost every case of tuberculous meningitis and miliary tuberculosis results from infection in the home. The patient with open infection who waits at home for a sanatorium bed knows the risk to which his family is being exposed, and when another member of the household becomes infected he will carry his remorse to the grave. The approach to the problem of tuberculosis is permeated with "apathy and a spirit of defeatism." There is urgent need of a nation-wide attack to end "the scandal of a preventable disease flourishing in a civilised community."

HOSPITAL ESTABLISHMENTS

THE Ministry of Health has arranged for expert groups to examine hospital establishments. As reported to the North West Metropolitan Regional Hospital Board last week, the reviews are to cover the staffs of boards and management committees and the administrative and clerical, medical and dental, nursing, and domestic staffs of the hospitals themselves. Boards and management committees are being invited to associate with the visiting groups any of their members and officers they may wish, and each of these groups, when reporting to the Minister, will put before him the views of the board or committee. The Minister will then decide the establishment, and hospital authorities will be required not to exceed this without first gaining the consent of the Minister in the case of staff appointed by boards, or of the board in the case of staff appointed by management committees.

ANTI HISTAMINE DRUGS AND THE BLOOD

NO ONE familiar with the composition of the anti-histamine drugs will be surprised to learn that they can cause toxic reactions in the blood and blood-forming tissues. As early as 1945 Clement and Godlewski¹ reported agranulocytosis in a girl, aged 13½, who had had 3 weeks' treatment for asthma with a drug resembling tripeleminamine hydrochloride ('Pyribenzamine'). Since then this complication has been described in four cases after hydrochloride,² in one (fatal) after mepyramine,³ and in one following the administration of metaphenylene hydrochloride ('Diatrin').⁴ This last case was in a man of 81 who was given the anti-histamine drug for chronic nasal congestion, the dose was not excessive—50 mg every 8 hours—but when he attended his doctor after having taken the drug for some 6½ weeks he was pyrexial and had a leucocyte count of 3600 per c.mm., with no polymorphs, 99% lymphocytes, and 1% monocytes. He was given penicillin, streptomycin, and blood transfusion, but it was 5 days before any granulocytes appeared in the peripheral blood, eventually he was none the worse for his experience. Drake⁵ noted that the anti-histamine drugs that had caused agranulocytosis all contained the benzamine linkage —N< and he pointed out that this group had been incriminated by Kracke in amidopyrine, which has a reputation for causing agranulocytosis. Some of the anti-histamine drugs, such as diphenhydramine ('Benadryl'), do not contain this dangerous group, and no case of agranulocytosis has so far been reported after their use. However, diphenhydramine has its own dangers, for Crumbley⁶ has described three cases of hemolytic anemia following its long continued administration.

Anti-histamine preparations are used for long periods chiefly in the treatment of asthma, hay fever, and some chronic skin diseases. These reports are a warning but, considering the widespread use of these drugs, especially in the U.S.A. where they are freely obtainable by the public, serious toxic reactions seem to be rare. In this country anti-histamine substances may be had only on a doctor's prescription—a precaution envied by some American physicians.

HORMONES AND PROSTATIC CANCER

ESTROGEN therapy of carcinoma of the prostate has been practised for less than a decade. This is too short a time for final assessment of a cancer treatment, but it is long enough for an interim review. Nesbit and Baum¹ describe a five-year trial of oestrogen therapy in 1818 cases at a number of American centres. Some patients were treated with oestrogens alone (in doses equivalent to 1–5 mg diethylstilboestrol daily), some by orchidectomy alone, and some by a combination of both methods. Control figures are provided by a series of cases which had no treatment. Judged by survival rates, hormone therapy was better than no treatment at all, but administered hormones alone were never so effective as orchidectomy alone, and usually the best results were obtained with a combination of the two. In cases without metastases this combined therapy gave a five-year survival rate of 44%, with orchidectomy alone the percentage was 31, and with oestrogens alone 29, only 10% of the controls survived. The presence of metastases heavily weighted the scales against success, in these cases the corresponding survival percentages were 21, 20, 10, and 6. In the symptomatic treatment of relapse, ringing the changes often brought a measure of success. Here also orchidectomy seemed more effective than administered oestrogens, but the difficulty of assessing and comparing symptoms undermines the value of this conclusion. The results over the whole series vindicate the belief that hormone treatment of prostatic cancer can prolong life.

RADIOTHERAPY OF ANKYLOSING SPONDYLITIS

SUCCESS in the treatment of ankylosing spondylitis depends on early and accurate diagnosis, but the symptoms may be so slight that the doctor is not consulted until years after the onset—even the patient with a completely rigid spine may recall no more than twinges of "rheumatism" or "fibrositis". Then the disease can assume many guises. In a youth with fever and joint pains it is likely to be labelled acute rheumatism. Reiter's syndrome accompanying spondylitis will strongly resemble gonorrhoeal urethritis and arthritis, and pain referred to the thorax or abdomen may lead to confusion with cardiac or pulmonary infarction, appendicitis, and the like. It follows that spondylitis should be considered in patients with a wide variety of symptoms, and where it seems a possible diagnosis the examination should include toe touching with extended knees, chest expansion, and X-ray films of the sacro-iliac joints.

The outlook for these patients may be vastly improved if 'Cortasone,' ACTH, or some effective substitute becomes plentiful, for the disease responds to these drugs as strikingly as does rheumatoid arthritis.² Meanwhile, radiotherapy is the mainstay of treatment, and in most cases it will rapidly relieve the pain. The wide field technique³ has been largely superseded by heavier dosage to a relatively small area, and though only the sacro-iliac joints are diseased most radiotherapists now treat the whole spine as well, because it almost always becomes involved later. The back is divided into areas which are irradiated separately: the sacro-iliac joints form one area, and the cervical, dorsal, and lumbar spine three or four, according to the patient's build. The precise dosage does not affect the results. At the Rheumatology Unit of the Royal Free Hospital a skin dose of 1200 r at 220 kV is given to each area in eight treatments spread over four weeks. A rather smaller skin dose is applied to any peripheral joints involved. The patients are admitted to the wards for this treatment, at any rate in the earlier stages, and they receive a high-calorie diet with abundant vitamin and iron, and weekly liver injections. A blood count is done every week, and a fall in haemoglobin below 11.0 g per 100 ml is an indication for blood transfusion. Thus the fatiguing and debilitating effects of X-ray treatment are largely avoided. The patient rests and sleeps on a mattress made flat and unyielding by fracture boards. To mobilise the costovertebral joints, he is given exercises which encourage costal breathing, while diaphragmatic movement is discouraged by manual pressure over the epigastrium. The spine is kept extended and kyphosis corrected by the "weight and counterweight" method⁴ in which the patient is suspended, face upwards,

from overhead bars by a canvas sling under his dorsal region, and his neck, arms, and legs are supported by spring slings, this arrangement allows him to extend his neck and limbs with the assistance of gravity but against the pull of the springs, which can be varied to suit each case.

The common complications of spondylitis are iritis and respiratory infections. The virus infections can be particularly troublesome, and radiotherapy seems to activate them, here 'Aureomycin' will often be of great value. In women, irradiation of the sacro iliac joints carries a heavy risk of subsequent sterility, for the usual X ray dose given to the ovaries to produce an artificial menopause is only 600 r. Even when the hip joints are treated with X rays there is likely to be at least a temporary amenorrhoea. At the Royal Free Hospital the sacro iliac joints are never irradiated in women of child bearing age.

FAILURE AT SHEFFIELD

PLANS were well advanced in Sheffield for turning a modern local authority clinic into a health centre. But the city council is unable to proceed with these plans because, after lengthy negotiation, the executive council can give no assurance that general medical practitioners will be available to staff the centre. This disappointing and regrettable conclusion sets back the chances of early health-centre experiments in industrial areas. No shortage of money or building materials was the difficulty here, for the clinic building lent itself to inexpensive but adequate adaptation. The opportunity was lost through failure to find ways whereby the doctors already practising nearby could be reconciled to the changes, in their customs and in their relationships with their colleagues, which they feared might follow the implantation of a health centre in their midst.

The Collings report¹ rightly urged that the highest priorities, both medical and economic, should go to improving conditions of medical care and professional life where they are worst—in crowded urban areas. So far this object has been defeated wherever it has been attempted, and for the moment it looks as though the only chance of our generation seeing group practice from health centres is to place them in new towns or on new housing estates and staff them with doctors who have no local interests to reconcile or animosities to forget. But the results of experiments of this kind, made under ideal conditions, would have only limited relevance to practice as it really is. At bottom, improvement in the professional life of practitioners depends on their willingness to coöperate, and the Sheffield decision provides more ammunition for those who hold that real progress will be impossible so long as there is competition for patients.

REMUNERATION DISPUTE

BECAUSE the claim for better remuneration of general practitioners remains unsettled, all such practitioners taking part in the National Health Service are being asked by the British Medical Guild to sign a form of resignation. These forms will not be handed in to executive councils unless 80% of practitioners express willingness to withdraw, and the decision whether or not to attempt this mass withdrawal will be made by the Conference of Local Medical Committees in December by which time the results may be known of investigations into (1) the total remuneration received by practitioners in the year ended March 31, 1950, and (2) the percentage of income which practitioners pay in expenses. The decision to plan for withdrawal was taken by this conference last June and was endorsed by the Representative Body of the B.M.A. at its annual meeting.² At the latter meeting Dr S. Wand, chairman of the General Medical Services Committee, declared that the important thing is that the betterment factor (on gross income) should be increased from 40 to 70%—an adjustment estimated to cost about £7 million per annum. If notices of resignation are handed in, the Minister of Labour must be informed that a dispute exists and he may then refer this to compulsory arbitration.

On Oct 11 the fee payable to the General Medical Council for first registration under the Medical Acts was raised to 11 guineas. The council was authorised to increase this fee under the Medical Act 1950. The fee for the registration of additional qualifications, including diplomas in public health, has not been raised.

EFFECTS OF CORTISONE IN THE RHEUMATIC DISEASES

DR HENCH'S LECTURE

ON Oct 5 Dr PHILIP HENCH, of the Mayo Clinic, addressed a meeting of the Windsor Medical Society at the Special Unit for Juvenile Rheumatism, Canadian Red Cross Memorial Hospital, Taplow, Bucks. The following is a summary of what he said.

RHEUMATOID ARTHRITIS

Two years ago, at a meeting of the Heberden Society, I spoke of the potential reversibility of rheumatoid arthritis, and now this possibility has been realised by 'Cortisone,' which can cause marked relief of symptoms in a few days in 95% of treated cases. Maximum subjective improvement occurs in up to 8 days, maximum objective improvement in up to 3 weeks, and maximum over all remission of the disease in all its clinical and biochemical aspects in 2-3 months.

The patients' strength, appetite, body weight, and mental and physical activity improve rapidly. There is a sense of well being, sometimes amounting to euphoria. Fever usually disappears. Rheumatoid nodules shrink and may become impalpable. An analysis of flexion contractures shows that 68% disappear in 3-21 days and 32% improve, according to the previous degree of fibrotic change. Even contractures of 2-3 years' standing have completely gone, and physiotherapy may complete a partial cure by cortisone. The responses to second, third, and fourth courses of cortisone are essentially similar. When treatment is discontinued symptoms return in 2-4 weeks, but not in all cases. The over all results are as follows: disappearance of over 90% of symptoms in 60% of cases, disappearance of 75-90% of symptoms in the rest—except in a very few severe cases where there is only moderate improvement.

There is a parallel reversal of laboratory findings. The sedimentation rate will become normal if treatment is continued long enough, but it should be noted that with cortisone, though not so much with A.C.T.H., there is up to 9 days lag before treatment or its withdrawal is reflected in a change in sedimentation rate. With cortisone and especially with A.C.T.H. the numbers of circulating lymphocytes and eosinophils are reduced, although with long periods of administration of cortisone this effect is decreased. The 17 ketosteroids are increased by A.C.T.H. and reduced by cortisone, while the 11-oxysteroids rise with both. The serum protein and the hemoglobin are unaltered. The plasma-electrolyte pattern does not show great changes unless courses of 200 mg a day, or more, are given for over a week. In such cases the blood bicarbonate percentage rises and the ionised potassium may fall to between 8 and 14 mg per 100 ml, whilst the chlorides may fall to less than 550 mg. These changes seem much less common when patients are allowed unrestricted diet. Serial biopsies of synovial membrane show improvement consisting in decrease in the cellular reaction and numbers of plasma cells and lymphocytes and in less fibrin deposition, less necrosis, and less oedema. However, in no case of rheumatoid arthritis so far studied has there been a complete reversal of the histological picture to normal.

RHEUMATIC FEVER

Rheumatic fever and rheumatic carditis present a different problem. One can imagine a hypothesis in which the susceptible rheumatic subject, sensitised by unknown inherited or environmental factors, develops what may be called the 'latent rheumatic state'. The latent rheumatic state, plus the presence in the body of the unknown irritant produced by the hemolytic streptococcal infection of the throat, react to give the clinical attack of rheumatic fever. This reaction is in two parts. The first part is exudative, with inflammation, oedema effusions into synovial cavities, and fever. It is relatively unimportant. The second is proliferative, with cellular infiltration, and later fibrous tissue formation in the sites of rheumatic nodules and in the connective tissue of the heart and its valves. Unless cortisone can suppress this proliferative reaction as well as the exudative, it is of no more use than aspirin. That it can do so is not proved but probable, for the following reasons. Firstly, the granulation tissue of rheumatic carditis is similar to that producible in experimental animals and to that of rheumatoid arthritis both of which are known to be suppressed by cortisone.

Secondly, certain significant cardiac murmurs have been reported by Massel et al. to have disappeared under treatment. And thirdly, in the short follow up studies so far available, new murmurs indicating fresh carditis have not appeared, and there has been no significant change in established murmurs. But it must be stressed that a much longer follow up time, 2-3 years, must elapse before judgment can finally be made.

There are good reasons for believing that the average duration of the latent rheumatic state is between 6 and 12 weeks. Under the influence of Δ^4 CTH or cortisone the latent rheumatic state and the unknown irritant are still present, though symptomless, for 6-12 weeks. If these hormones are given until the end of the period of the latent rheumatic state, no withdrawal relapse occurs. If the hormones are withdrawn before, then a relapse will occur which will last until the natural end of the latent rheumatic state. It must be emphasised that rheumatic fever is not "cured" the duration of the latent rheumatic state is not shortened, and subsequent recurrences are not prevented by cortisone. The hope for the future lies in giving cortisone to suppress the body's reaction during the latent rheumatic state, and in the oral penicillin chemoprophylaxis of streptococcal infections in susceptible subjects.

OTHER FORMS OF ARTHRITIS

Other forms of arthritis have been treated. Of patients with osteoarthritis 50% have shown satisfactory responses. Symptoms of acute gouty arthritis are rapidly suppressed, although they may relapse on drug withdrawal. Chronic gouty arthritis shows little structural change, despite symptomatic improvement, and tuberculous arthritis, though symptomatically relieved, continues to show active tuberculous and positive culture in biopsy material from the affected joint.

SIDE EFFECTS

These powerful hormones, if given for long enough may produce undesirable side-effects. Females, especially menopausal or adolescent, show more than males. Side effects are rare in diseases such as acute gout or acute rheumatic fever, controllable by short courses of treatment, but are more common in patients receiving long continued treatment for chronic disease such as rheumatoid arthritis. The first treated cases of this disease received rather large doses and about 25% showed significant side effects. In the current series the incidence is about 8%, mainly because lower maintenance doses of about 65 mg or less daily are used. Minor side effects such as euphoria and rapid mood swings are common and of little significance. Rounding of the face, oedema of the legs, acne, hypertrichosis, and stria distensae occur occasionally but rarely interfere with treatment. Few side effects present emergencies, most develop slowly and can be detected early by close observation but a few demand special attention. Excessive salt and water retention may add dangerously to the load on an already failing heart. Patients who are also diabetic show a decreased carbohydrate tolerance and require less insulin. Major psychotic changes have occurred but are rare, and are believed to be due more to a pre-existing psychotic personality than to treatment. Osteoporosis in the elderly, combined with suddenly increased muscular activity, may lead to spontaneous fractures.

SUBSTITUTE FOR CORTISONE

In the hope of finding a drug cheaper, safer, and more easily available than cortisone, over 50 closely related steroids and many adrenal extracts have been tried. None, except compound F, has been found to possess antirheumatic activity in our hands, or in the hands of critical rheumatologists experienced with cortisone. This includes pregnenolone, Δ^5 pregnenolone and desoxycorticosterone with or without ascorbic acid. Several of these compounds differ only in one particular from cortisone. As a result, we can say that the antirheumatic properties depend on

- (1) A ketone group at C 3
- (2) A double bond between C 4 and C 5
- (3) A ketone or hydroxyl group at C 11
- (4) A hydroxyl group at C 17
- (5) A ketone group at C 20
- (6) An hydroxyl group at C 21

In the absence of an effective substitute for cortisone we must learn to obtain the maximum desirable with the fewest unwanted effects. Some preliminary successes have been obtained in this direction. Rounding of the face, acne,

hypertrichosis, and "buffalo hump" can be controlled by 10 mg of oestrogens per week. Oedema and fluid retention often disappear spontaneously if hormone treatment is continued, but can if necessary be controlled by diuretics, by potassium chloride 6 g per day, and by a restricted salt and fluid intake. Undue nitrogen loss, less common on unrestricted diets, can be controlled by 25 mg of testosterone each day. Psychotic manifestations may require temporary interruption of treatment, or, sometimes stronger measures such as shock therapy. We must learn to co-operate with, rather than dominate or supplant, the functions of the pituitary-adrenal system.

METHODS OF TREATMENT

Various plans of administration have been used. No plan yet emerges as consistently the best. In one plan treatment is given in full doses for short courses of up to 3 weeks which are abruptly begun and abruptly ended, and repeated when symptoms recur. This has the advantage that the physician knows what is happening to the disease process underneath the hormonal suppression, and occasionally a relapse of the disease has not occurred for many months after treatment ceased. But patients, once freed of their disease, tolerate very poorly even its partial return, and have great difficulty readjusting themselves. A second plan gives fully suppressive doses during a short initial period, followed by maintenance doses gradually reduced to a minimum which prevent recurrence. This saves the patient from the misery of recurrences but is costly and requires close supervision. Even a change in dosage from 50 mg a day to 100 mg on alternate days may need careful management. A third plan alternates courses of cortisone with courses of Δ^4 CTH. In theory this should produce less secondary suppression of the adrenal or pituitary glands.

THE FUTURE

There are many promising new developments under way. Briefly, these are the improved methods of producing cortisone and Δ^4 CTH, the development of long acting Δ^4 CTH and the development of Δ^4 CTH peptides, the potentiation of cortisone with insulin, the production of radioactively labelled cortisone and its use in research, the development of compound F (which has as yet not been successfully synthesised), and the studies on oral cortisone.

In conclusion, it should be added that at the Mayo Clinic these hormones are not yet used in routine treatment. But one cannot remain academically aloof to the millions of arthritic patients who ask "Can we get the hormones as a safe treatment, and if so, how soon?" Many investigators believe that these drugs can now be released for practical application in conditions requiring relatively short term treatment. The price of cortisone has already fallen from 1000 dollars to 50 dollars a gramme, and it is now available in every large American hospital. In the management of chronic diseases, and especially in rheumatoid arthritis, current investigations may reveal the limits of its usefulness. Much remains to be learnt, but a satisfactory beginning has been made through the correlated efforts of many investigators in many branches of science. Whatever the destiny of these hormones in practical therapy they demonstrate clearly the reversibility of certain disease processes formerly regarded as relentlessly progressive, and in particular they are powerful tools with which we can investigate many problems of aetiology and treatment in a wide variety of diseases.

In England and Wales notifications of poliomyelitis during the week ended Oct. 7 were paralytic 241 (222) non-paralytic 112 (109) total 353 (331). Figures for the previous week are in parentheses. In the week under review non-paralytic cases formed 23.5% of the total.

From Letters to the Editor

Propagation of the Unfit—In the lecture published on Sept 30, Professor Penrose restates his ingenious thesis that our population is largely self regulating for its genetic endowment for intelligence. The relatively heterozygous individuals of about average intelligence have, he suggests, a naturally higher fertility than the more homozygous intelligent and dull individuals. If this is correct, then not only is a high net fertility of the dull of little lasting importance, but also any eugenic plans for achieving a fairly rapid rise in the average genetic endowment of the population for intelligence will be frustrated by the infertility of the intelligent. In so far as net fertility is under social control it will, however, still be possible to some extent to maintain the average level above that to which it would naturally revert, by measures to raise the net fertility of the intelligent to its maximum and to depress further the fertility of the dull. One might argue that at the moment the reverse process is occurring from incomplete data it seems that the highest net fertility lies with a group whose intelligence is well below the average.

But before accepting Professor Penrose's thesis, however attractive its theoretical basis, one would like to have the nature of the reduced net fertility of the dull and the intelligent demonstrated. There are figures from America (Indianapolis survey) which imply that differential fertility in relation to economic status depends almost entirely on the relative success with which family size is planned; there was little difference in the degree of fecundity or the size of family desired, but considerable variation in the number of unplanned pregnancies. Obviously psychological factors are responsible for causing social classes 1 and 2 as well as the more intelligent in other social classes in Great Britain to plan the size of their families at well below replacement level, but it seems likely that these psychological factors are determined more by environment than genes. Further, we cannot be sure that these psychological factors are any less strong in the rest of the community until they too are in a position to plan the size of their families effectively. My own guess is that when we have an easy foolproof method of controlling conception which does not offend religious or aesthetic susceptibilities, the present differential fertility in relation to intelligence will disappear. I do not think that we shall then find either dullards or psychopaths deliberately choosing to have large families and I shall be surprised if there is not ample fecundity available to make it worth while to encourage parents who are likely to produce children well adapted to life in a social democracy, to have large families.—C O CARTER, M.R.C.P. (Orpington Kent)

The Food We Eat—There is much to support the suggestion by Dr Ffrangcon Roberts (Sept 30) that a change is taking place in our feeding habits which may be having physiological as well as social consequences. Rationing has probably expedited a social trend apparent before the war—nowadays the popularity of snack bars is obvious. Carbohydrate with a relish of some kind unfortunately forms the basis of most snacks; in fact, these are strikingly similar to the meal of the Oriental whose diet is notoriously deficient in fat and first class protein—a circumstance believed to exert a profound effect on national vigour.

In days gone by, most artisans started the day with a breakfast in which pork figured largely. The midday meal was usually of the packed variety and though simple, was of a nutritional quality now hard to achieve. In the evening a third meal was taken. Today, for breakfast many get hardly anything at all, or hurriedly eat a cereal. Little wonder that tea breaks and other interruptions are frequent. Often these interludes are decreed but probably they reflect an unconscious desire to satisfy physiological demands. Break privileges may be abused and restrictive practices may be in operation but here I am concerned only with the medical side.

Anyone who has observed, or worked with men doing continuous work of one kind or another recognises that in recent years despite a will to work staying power has deteriorated. In the evening an insidious fatigue seems to bring activities to a close whereas in the past overtime would willingly have been worked—and sometimes particularly in rural areas still is—not necessarily for the pecuniary reward but for the satisfaction a completed task gives. The extra rations granted to certain manual workers is an official admission that something additional is needed but somehow

in practice the desired end is not achieved. When a man decided for himself the diet which best suited him in his work he could get it. Popular exhortations to increase production may prove more effective when the protein bait is something more than an extra piece of cheese.—W R THROWER M.R.C.P. (London, W 1)

Hazards of the Aged Hip—Your leading article of Sept 30 draws attention to a matter of increasing importance. At Worcester Royal Infirmary, which serves a population of 150,000 we have in seven years admitted 120–130 of these cases, of which 116 have been treated by open operation and some form of nail or nail plate. From 1944 to 1949 we averaged about 14 cases a year, but this year we have already operated on 30 in nine months. Every case is considered a justifiable risk for operation unless the patient is moribund after observation for three or four days. While it is agreed that traction alone is suitable for the trochanteric types of fracture we are driven by shortage of staff and beds to prefer operation in order to ease the nursing of these patients and to get them ambulant on crutches and out of hospital at the earliest possible moment. The average stay in hospital under this régime is about three weeks and the operative and post operative mortality is negligible—possibly 1 or 2%. Though accurate figures have not yet been worked out, my impression is that 60–70% of our cervical fractures achieve bony union. Non union, due to interference with the blood supply and aseptic necrosis of the head, is an unsolved problem for the remaining 20–30%. For cervical cases with non union, a McMurray type of osteotomy after removal of the nail gives excellent results, though this condemns the patient to a tedious three months or longer in a plaster spica and adds to the burden of nursing. Trochanteric fractures fixed by a Capener or McKee type of nail plate seem always to unite quickly.—NORMAN DUGGAN, F.R.C.S. (Worcester Royal Infirmary)

Theory of Barbiturate Action—Dr Dalton's speculation (Oct 7) is difficult to reconcile with the fact that, with all barbiturates so far tested anaesthesia results in an increase in the acetylcholine content of brain (Tobias J M, Lipton M A, Lepinat A A *Proc Soc exp Biol, N Y* 1946, 61, 61. Richter D, Crossland, J *Amer J Physiol* 1949, 159, 247. Crossland, J Unpublished observations). This effect is regarded as secondary to the decrease of nervous activity during anaesthesia, since a similar, though smaller, increase is found during natural sleep (Richter and Crossland 1949). Such a decreased liberation of acetylcholine, rather than reduced synthesis, is the more probable explanation of the finding of Velazquez and Elio Membrado that the amount of acetylcholine in the cerebrospinal fluid (c.s.f.) of dogs is reduced during anaesthesia (*Pharmacoterap actual, Madrid*, 1944 1, 28). Conversely the finding by Tower and McEachern (*Canad J Res* 1949, E27 120) that in cases of epilepsy acetylcholine often appears in the c.s.f. in amounts depending on the frequency of the seizures, is likely to be explained by increased release of acetylcholine since there is little evidence to associate epilepsy with accelerated synthesis of this substance by the brain.—J CROSSLAND, M.A. (Neuropsychiatric Research Centre, Whitechurch Hospital, Cardiff)

Enuresis and Hypersomnia—Dr Ström Olsen has suggested (July 22) that in adults enuresis and hypersomnia constitutes a syndrome of central origin but he hesitates to claim that a similar syndrome is to be found in children (Sept 30). I have shown that in some cases of enuresis there are uninhibited contractions of the bladder which do not reach consciousness and which may to some extent be inhibited by drug treatment (*Ann R Coll Surg* 1949 5, 5). Such has been the rationale of treatment with ephedrine and even with belladonna but perhaps we have too often assumed that any benefit is due to the local action of these substances. In patients benefited by this treatment the structure and function of the bladder are so often normal that the effect is probably due to the drug's stimulating and sleep diminishing effect. The greatest advance in the treatment of true functional enuresis has been the introduction of Dextedrine. Bearing in mind that one in three cases of enuresis coming to hospital has some organic factor, among the remainder the cure rate is very high when dextedrine is used in conjunction with ordinary toilet training. Hypersomnia enuresis and bad school reports go together and often disappear together.—D F ELLISON NASH, F.R.C.S. (London, W 1)

Tuberculin Surveys—Dr Hounslow and Dr Macdonald have asked, in their letter of Oct. 7, if there can be any advantage "in delaying further a major investigation into the level of tuberculinisation of our own population." A large scale tuberculin survey covering 22 different areas in England and Wales was organised recently by the Medical Research Council with the active co-operation of the staff of many local health authorities and regional hospital boards. Nearly 100,000 children and young people between the ages of 5 and 20 were tuberculin tested, and the results are at present being analysed—M. DANIELS, M.R.C.P., secretary, M.R.C. Tuberculin Survey Committee (Medical Research Council Laboratories, London, NW 3).

No Tools—Under this heading (Sept. 23) you do scant justice to the public health authorities. At the time of the inauguration of the dispensary scheme the sanatorium alone had proved a failure—and, owing to the adoption of graduated work, a danger. The same could be said of tuberculin treatment. Little or nothing had been said about the value of rest. But in the counties of Rutland and Peterborough the surprising value of rest was made known to the public by the war cry "take away his trousers and his lungs will look after themselves," and as far back as 1915 this was elaborated by my undertaking artificial pneumothorax treatment in the patient's home. My first patient lived for over twenty years, the second is still alive, and over 40 were so treated without requiring sanatorium treatment. It goes to prove that elaborate buildings are not needed. It will be years and years before additional sanatoria can be built, and meanwhile a very large proportion of chest cases could be treated in their homes or in open air shelters adjoining their homes—CHRISTOPHER ROLLESTON, M.R.C.P. (Ketton, Stamford, Lincs.)

Incidence of Sprue Syndrome—In collaboration with Dr J. R. Fountain I published (*Brit. med. J.* 1950, 1, 1157) an etiological study of some 2000 cases of the sprue syndrome (tropical sprue, idiopathic steatorrhoea, and coeliac disease) who received priority rations between 1943 and 1948. We produced evidence that the syndrome might be conditioned by a genetic factor which may be accentuated and brought to light by a variety of environmental agents. The rarity of the syndrome (one case of idiopathic steatorrhoea per 700,000 population over 15 years of age, and one case of coeliac disease per 135,000 population below that age) makes it unlikely that any individual will see sufficient cases to throw additional light on the etiological importance of the genetic factor. I am therefore appealing to medical men in all parts of the world to help in this investigation by sending me any information regarding two or more cases of the syndrome in a single family. I should also be grateful for information which would help to answer the question "What happens to children with coeliac disease?"—i.e., what percentage die, recover, or appear in adult life as cases of idiopathic steatorrhoea?—Prof. L. S. P. DAVIDSON, F.R.C.P. (Department of Medicine, University of Edinburgh.)

Status of Tuberculosis Workers—Workers in tuberculosis will be dismayed by the Ministry of Health's announcement concerning the posts that may suitably be filled by senior hospital medical officers. It appears that, under this ruling, doctors who have specialised for years in this field will very seldom be able to attain consultant rank. In particular those who choose to remain in chest-clinic work are unlikely to be eligible for consultant status. This decision follows discussions with professional bodies, and it is difficult to avoid the conclusion that not only the Ministry of Health itself but also consultants in other branches of medicine are determined to maintain the degraded position of the tuberculosis service. It was hoped that, with the advent of the N.H.S., this position would be radically altered and all doctors who had made a single speciality their life work would be considered on equal terms according to individual merit. Here, however, we have the singling out of a specific branch of medicine (among others, such as geriatrics and infectious diseases) as a speciality in which, whatever one's personal achievement, the likelihood of consultant grading is remote. With the present shortage of beds and the increase in responsibility falling on the chest clinic physician and his staff, this decision is extremely short-sighted. Tuberculosis today forms the greatest problem facing the health service, but until tuberculosis workers are given the recognition which their work and responsibilities demand, there is little hope of drawing the best men into this work—PETER STRADLING, M.R.C.P., consultant chest physician, Hammersmith, London.

In England Now

FRIDAY morning used to be one of unalloyed pleasure. I would get up at leisure—my hospital round is later than on other days—and enjoy an idyllic breakfast ploughing steadily through the *Lancet* and the *Times*, with a final glance at the *New Statesman*, as I munched my toast and marmalade. With careful timing I could get down just after the children left for school but before the breakfast things were cleared away. Then all was changed, simply because your newborn contemporary, the *E-gle*, also comes out on Fridays. I tried every expedient, even telling our newsagent to hide in the bowels of the *Times*, but it was no use, the child always got there first, and they would either whisk the paper off to school, without allowing me so much as a glimpse of Dan Dare, Spaceman of the Future, or add insult to injury by shrieking a brief synopsis as they flashed by. Life seemed bleak indeed until I hit on the device of beginning my Friday's round in the children's ward. Every child seems to have a copy, and I can comfortably get through the week's instalment as I pause at each bedside to pass the turn of day or palpate an abdomen. I'm afraid the unwelcome sparkle in my eye has given me away and my stock has gone down with the nurses, but the few children who have tumble to it now greet me as one of the Initiated—a fellow space traveller.

* * *

The vast physiology theatre at the medical school was crammed to the roof for the first meeting, on Oct. 4, of the reconstituted Manchester Medical Society. Mr Wilson Ho, the president, traced the history of Manchester medical societies from the late 18th century, and the Lord Mayor commented without surprise on the number of occasions the doctors forgathered on licensed premises. As president of the Royal Society of Medicine, Lord Webb Johnson presented Mr Hey with a document conveying the society's good wishes, the Vice-Chancellor hoped that the society would help to bridge the growing rift between specialist and general practitioner. Prof. Hilda Lloyd suggested that Manchester had more or less founded the Royal College of Obstetricians and Gynaecologists, and blessings were pronounced by Sir Cecil Wakeley for the Royal College of Surgeons, by Prof. Crichton Bramwell for the Royal College of Physicians, and by the president of the Liverpool Medical Institution.

Over 600 people went to the reception in the Whitworth Art Gallery in the evening. Those of them who hoped that the society would be re-launched with champagne might have thought differently if they had known how hard the treasurer found it to pay for the light refreshments.

* * *

Most of the pituitary glands of American cattle find their way into the processing plants of a great commercial laboratory, whence they emerge in part as ACTH. But I was perturbed to find that this firm seems to claim a controlling interest in the human hormone in vivo, for one of its publications refers to the "alarm reaction" as the sudden and marked endogenous ACTH (Armour) stimulation of the adrenal gland during environmental stress. Must we pay royalties to the U.S. every time we get into trouble? If so, financial stress will create a vicious spiral.

News

As part of the general settlement of the salaries of hospital nursing and midwifery staff, agreements have been reached by the Nurses' and Midwives' Whitley Council for revised rates of pay for departmental sisters, superintendent male nurses, night sisters, night superintendent sisters, male tutors, assistant matrons, deputy matrons, and matrons in hospitals other than mental hospitals, mental deficiency institutions, and maternity hospitals and homes (N.M.C. (50) 8). New rates have also been fixed for superintendent and deputy superintendent nurses (now graded as matrons and assistant matrons) working in National Assistance institutions which have beds for the chronic sick.

On Oct. 12 the honorary medal of the Royal College of Surgeons of England was presented to Lord Webb Johnson for his many generous acts and continued labours in the interest of the college during his eight years of presidency.

The National University of Ireland has conferred the honorary degree of D.Sc. on Dr Philip S. Haechel and Mr E. O. Kendall, D.Sc. of the Mayo Clinic, Rochester, Minnesota, in recognition of their contributions to medical and biochemical research with particular reference to their work on "Cortisone".

Lord Nuffield has been elected president of the British Rheumatic Association

The Rockefeller Foundation has made grants of over £20 000 for studies in London, Cambridge and Bristol in human heredity, anthropology and anatomy

Television has been successfully used in Philadelphia for the long range examination of X ray films. According to B U P the image is in some respects better than the original

The annual meeting of the British Orthopaedic Association will be held at Friends House, Euston Road, London N W 1 on Oct 25, 27 and 28

Speaking at the annual conference of the National Smoke Abatement Society held last month at Margate, Dr J S G Burnett M O H for Preston described instances of increased mortality in this country which had followed smoke fogs. But apart from these periods of limited and heavy pollution there was always some pollution in the air which had harmful effects over long periods. Mr R E Waller who is working in the pathology department of St Bartholomew's Hospital said that examination of town smoke had shown that cancer promoting substances were always present in trace amounts. Mr D T A Townsend D S C, director-general of the British Coal Utilisation Research Association gave the first lecture named after Dr H A Des Vœux, the founder of the society.

The professional nurses and midwives conference held each year under the auspices of the *Nursing Mirror* will take place from Oct 23 to 27 at the Seymour Hall, Seymour Place, London W 1. Viscount Addison will preside and the speakers will include Prof Hilda Lloyd, F R C O G and Sir Cecil Wakeley, F R C S.

A *Handbook for General Medical Practitioners* which is being issued by the Ministry of Health to doctors on the lists of executive councils provides comprehensive information about the operation of the N H S as it affects the practitioner.

CORRIGENDUM *Treatment of Fibrositis with Adrenaline, Ephedrine and Belladonna Creams*—In Dr Howell's article of Sept 23 (p 395) the formula for the ephedrine cream should read: Ephedrine hydrochloride 1 part, emulsifying wax 20 parts, wool fat 10 parts, chlorocresol 0.05 part, water to 100 parts.

Births, Marriages, and Deaths

BIRTHS

DAVIDSON—On Sept 21 at Anstruther the wife of Dr W G Davidson—a son
FIGGIS—On Oct 9 the wife of Dr M M Figgis—a daughter
ROBINSON—On Oct 13 at Danby, Yorks the wife of Dr Robert Robinson—a son
RODGER—On Sept 28 the wife of Dr D E Rodger—a son

ACADEMIC AND EDUCATIONAL

Empire Rheumatism Council Post-graduate weekend course at Apothecaries Hall, Nov 17-19. Fee 2 gns with application to Gen Secretary, Tavistock House (N), Tavistock Square, W C 1

Institute of Orthopaedics Course in diagnostic and prognostic methods in orthopaedics, Nov 6-11. Fee 7 gns. Apply Dean 234 Great Portland Street, W 1

Institute of Ophthalmology W C 1. Sr Lecturer in Bacteriology with experience of virus work (£1250-£1000-£1750). Apply to Secretary (closing date Nov 10)

London University Research Grants for materials and apparatus. Apply Secretary Central Research Funds Committee, Senate House, W C 1, by Nov 30

Birmingham University Chair of Obstetrics and Gynaecology (£2250-£2750, eligible for distinction award). Apply to Secretary (4 weeks)

Glasgow University Jr Asst Department of Midwifery. Apply to Secretary (closing date Nov 11)

Liverpool University George Holt Fellowship in Physiology. Gastro-enterology research. Medical and Science graduates apply to Registrar

Hospital for Sick Children W C 1. Research Fellowship for Pathologists to Investigate Malignant Disease in Childhood. Tenable 1 year (£1000). Apply to Morbid Anatomist

Newcastle upon Tyne R H B Fellowship for survey of children's accommodation. General Mental, and Mental-deficiency hospitals (£1300). Apply to S.A.M.O. (28 days)

St Andrews University Professor of Surgery, in Senior Medical School, Dundee (£2750). Apply to Secretary (closing date Jan 15)

Nutrition and Antibodies

It now seems that the relation between nutrition and antibody production is less close than might be expected. True, GELL¹ found that well nourished British soldiers had better antibody responses than half-starved German civilians, but he remarked that the differences were slight. BALCH² has now measured the diphtheria antitoxin production of two groups of patients whose nutritional state differed widely.

One group comprised 25 severely ill patients, many with advanced malignant disease and most with low serum protein levels who had lost up to 40% of their normal body weight. In other words they were comparable to emaciated victims of Belsen.

The other group contained 19 well nourished subjects of whom 5 were in good health, 6 had an inguinal hernia and 8 had either cerebral vascular accidents or cardiovascular disease without cardiac failure. All had retained normal weight for at least six months, and their disability was not of a kind to influence their nutritional state.

BALCH chose diphtheria antitoxin as the test antibody because the antigen—diphtheria toxoid—can be had in highly purified form, because in immune persons the antitoxin response is high and relatively uniform and can be accurately estimated even in low concentration, and because, with purified toxoid, the antitoxin is the only antibody produced and its concentration in the serum is thus a measure of the patient's total capacity to produce circulating antibody. All patients of the two groups were first proved to be Schick-negative, and each then received intramuscularly 42 Lf (0.12 mg) of toxoid. Thereafter blood antitoxin levels were ascertained at three day intervals for at least three weeks, and in some patients at longer intervals until death. A rise in circulating antitoxin was usually noted within four days of the toxoid injection, with a maximum response between the fourteenth and twenty-fourth day. As in all experiments of this kind, the amount of antibody produced varied greatly between one patient and another, but there was no indication that in the depleted group the response was smaller than in the well-nourished group; indeed, the trend was in the opposite direction. Antibody response did not seem to depend on age, on serum protein, serum-albumin, or serum globulin level, or, surprisingly, on antibody level before the test dose of antigen was given. A number of patients showing the poorest antibody response did not acquire infection, whereas others developed infections although their antibody production was normal.

BALCH concedes that his results do not show whether diets rich in protein may enhance antibody production. Such diets have been advocated by CANNON and his colleagues³ for preventing infection after surgical operations on nutritionally depleted subjects. BALCH doubts, however, whether antibody production is of prime importance in postoperative infections. Wound sepsis, hypostatic pneumonia, peritonitis, and genito-urinary infections are more probably caused by interference with the circulation than by failure to produce antibodies. CANNON's conclusions are also open to question because in his investigations animals were

mostly subjected to an extremely low protein intake—often 1–2% of the diet—and the consequences of such a regime may not indicate accurately what happens in the nutritionally depleted human. Furthermore, there is evidence that the relation of nutrition to antibody production may be more subtle than that suggested by CANNON, who holds that protein depletion means failure of antibody production and that this failure can be corrected by protein repletion. For example, STOERK et al.⁴ showed that pyridoxine-deficient rats produced less antibody to sheep erythrocytes than rats given a complete diet (normal controls) or a diet reduced in quantity to equal that eaten by the pyridoxine-deficient animals (manitox controls). A similar finding has been reported by AXELROD et al.⁵ and by AGNEW and COOK⁶ with sheep erythrocytes and typhoid H antigen. Like BALCH, STOERK et al. and AGNEW and COOK observed that the manitox controls tended to produce more antibody than the normal controls. Pyridoxine deficiency interferes with amino acid metabolism and may thus hinder globulin synthesis, and STOERK et al. suggest that this may impair antibody production, perhaps directly and by causing lymphoid atrophy, which is a feature of pyridoxine deficiency, the importance of the lymphocyte in antibody production is now well established. For the present, therefore it would seem that reduction of the dietary protein is less likely to hinder antibody production than is interference with protein metabolism. We still know nothing about the optimum intake of protein for antibody production or about the effects of a rapid, compared with a slow, turnover of globulin. Meanwhile, we have to bear in mind that antibody production is not synonymous with resistance to all infections.

Distinction Awards

Not least important of the many ways in which the N.H.S. differs from the conventional State medical service is its method of paying the consultant. From the time of his appointment, after 14 years or more of medical training, his remuneration rises automatically to a maximum of £2750, which may be reached at the age of 40. Thenceforward any increase depends on his securing one of the three grades of distinction awards offered to a third of the whole body of consultants, chosen by a mainly professional committee. This committee reaches its decisions after considering recommendations from different groups of colleagues who know the candidate in different capacities, but it also takes account of the desirability of spreading the awards suitably among the specialties, and likewise (since one of the aims of the service is to improve consultant services at the periphery) among the geographical regions. Nobody would claim that this combination of cross bearings and rationalisation will always work equitably, and experiment in the next few years may show that professional opinion, collated in this way, ignores real merit almost as often as the fee paying public ignored it.

2. Balch H H. *J Immunol* 1950; 64, 397.

3. Cannon P R, Weller R W, Woolridge R L, Benditt E P. *Ann. Surg* 1944; 120, 514. Cannon P R. *J Amer med Ass* 1945; 123, 350.

in the past. But the awards are, after all, additional to a competence and if, like marriage, they are something of a lottery, they should, also like marriage, tend on the whole to reward the worthy. If a financial incentive is still useful in medicine, they provide it within the service, they introduce an element of flexibility into a system that might otherwise be dismally rigid, and we know enough of those already made to say that some have gone to first rate men whose modesty has forbidden expectations.

In the House of Lords last week Lord MORAN, as chairman of the Awards Committee, described how the awards are allocated, and pointed out that they are an integral part of the remuneration of consultants—not something that could be removed quite easily either as an economy or because of inconvenience caused, for example, to the universities. The N.H.S. in England, Lord MORAN said, has at present only 56% of the specialist establishment which the Ministry of Health thinks it will ultimately need. "Medicine, like other professions and other industries, must appeal competitively for the man of promise," and he felt sure that "if it were not for these awards we should not compete successfully." With few exceptions, in his opinion, consultants are in favour of the awards scheme and would be shocked if it were withdrawn. They signed their contracts on the understanding that after they

reached the peak remuneration of £2750—perhaps at the age of 40—there would still be a chance of financial advancement, and deep discouragement and disquiet would be caused if the agreement were for any reason dishonoured before the scheme had even been tried.

"If the financial circumstances of the country, as once before, meant that it was necessary to make a percentage reduction in the salaries of every profession, then medicine would gladly bear its share, but to take a fraction of a single profession and to confiscate a considerable proportion of their income is, I think, hardly in accordance with the elements of justice."

We share Lord MORAN's view. We think it right that exceptionally able consultants should be able to earn fairly large incomes, without looking for them in private practice. We recognise that there are cogent objections to the new arrangement, and that it would have been far simpler to pay consultants as though they were Civil Servants, but we believe that an innovation of this potential value deserves full trial, and we should deplore any attempt to interfere with it soon after it has made its difficult start. With surtax at its present level, the experiment costs the nation little, and we retain our hope that in a few years, with such modifications as may be needed, the awards system will win general approval as a useful departure from precedent, applicable possibly in other branches of medicine and also in other professions.

Annotations

THE HARVEIAN ORATION

THE fresh light shed on Harvey's life and work by successive Harveian Orators inspires increasing admiration. It was only fitting that Sir Leonard Parsons, F.R.S., in his oration last week, should discuss the contribution made by Harvey and his contemporaries to paediatrics, with particular reference to that comparatively little known work, *De Generatione*. This, as the orator observed, contains a wonderful description of the development of the human embryo from the eighth week of intra uterine life onwards. It also suggests that rickets was so prevalent in England in the 17th century that children walked and talked much later than they do now—a hypothesis further supported in the writings of Shakespeare, who makes the Nurse exclaim with wonder of the three year old Juliet—

"For then she could stand alone, nay, by the rood,
She could have run and waddled all about."

Harvey is believed to have influenced Glisson in his decision to take up medicine, and so he can be given some indirect credit for Glisson's work *De Rachitide*, which appeared in 1650. Another close friend, it is thought, was Sir Thomas Browne, whose writings touched on rickets but whose principal contribution to paediatrics lay in the antenatal field, certain of his statements can almost be taken to anticipate the effects on the embryo of dietary deficiencies and infection in the mother. Finally, the orator turned to Sydenham and contrasted his restatement of the value of pure observation with Harvey's emphasis on experiment. It was Sydenham who first described rheumatic fever in detail—though without mentioning the state of the throat in this condition—and it was the combination of his and Harvey's methods which raised British medicine to its greatest heights.

CONFERENCE ON RADIATION HAZARDS

THE conference organised by the new Institute of Biology and the Atomic Scientists Association, with support from the British Association, at the Royal Institution on Oct 20-21 opened with symposia on the biological effects of radiation and the protective measures used against any kind of harmful nuclear radiation. These prepared the way for the geneticists to discuss the hazards of radiation to the general population. Several speakers insisted that those who control the output and distribution of radioactive materials or other sources of dangerous radiation should be animated by a high sense of duty. In the geneticists' view, since experimental mutations caused by X rays are detrimental, if such mutations occurred in man and were maintained for many generations the prospects for the human race would be gloomy, some even said that man already has quite enough genes for natural selection to play on, and more would be an encumbrance or

worse. The last symposium, on atomic energy and the future, somewhat lightened the gloom by emphasising that there is no proof that deleterious mutants are produced in man by radiation, so we can take heart provided we also take precautions. In the final session there were strong expressions of opinion on the still greater hazards facing the scientist in the cloud of secrecy which is spreading over his work and which threatens his heritage of integrity and his traditional desire to reveal the truth. The atomic scientists were reminded that evil may arise from their studies. Without them the atomic bomb would not exist, they have thus become a menace to civilisation and suspect by the great body of the public. The plea behind these remarks was for action at the highest level to put an end to the prostitution of science.

ALCOHOL AND THE MOTORIST

CONVICTIONS are not easily obtained under section 15 of the Road Traffic Act, 1930, which lays down penalties for "Driving, or attempting to drive, or being in charge of a motor car on a road or other public place, while under the influence of drink or drugs to such an extent as to be incapable of having proper control." The driver's capability of having proper control has usually to be judged from the opinion of police and medical witnesses, and in borderline cases their evidence is often conflicting because the police describe the accused's condition when he was arrested, whereas the doctor does not examine him until he is charged, which may be some time later. Dr Gorsky¹ strongly disapproves of acrobatic tests for drunkenness, such as walking along a chalk line or repeating difficult phrases, which confuse the nervous and are sometimes remarkably well done by the drunken. Alcohol affects a man's car-driving long before the stage of dysarthria and incoördination, the driver who faultlessly performs all the mechanical movements of driving may yet be dangerously defective in judgment, reaction time, and consideration for others, on which avoidance of accidents largely depends.

The alcohol content of the blood and urine, or of the breath, which is now being studied in America,² will reveal how much alcohol the driver has consumed, though delayed absorption may lower the findings in habitual drinkers, but the intoxication produced varies widely in different people and circumstances. Nevertheless, in Sweden the blood alcohol level is always estimated when motorists are charged with drunkenness or involved in an accident, and a fine follows automatically if the level is over 0.08%, while if it exceeds 0.15% the punishment is up to a year in gaol. In Denmark, too, even if the clinical examination is satisfactory, a blood-level of 0.1% will earn the motorist 14-40 days imprisonment.

¹ Gorsky A. *Med J* 1950 18 48

² Hargreave R N, Forney R B, Barnes H B. *J Lab. clin. Med* 1950, 36, 306

In New York where the blood urine, or breath is analysed for alcohol within two hours of the motorist's arrest, and no medical examination is made, a blood level of 0.05% or less is *prima facie* evidence that the accused was not intoxicated, but findings between 0.05 and 0.15% are not *prima facie* evidence either way. There is no such definite rule in this country, though very low or very high blood levels will usually be conclusive. Otherwise the doctor who examines an arrested motorist must build up his conclusions from a multitude of clinical findings. Only occasionally will the magistrate be convinced by such observations as that the accused could eat a fried egg next morning (see p. 494).²

The antinistamine drugs have complicated the picture. Some of them, though they do not cause intoxication by themselves, can intensify the action of alcohol, so that a quantity which normally has little effect will produce drunkenness. The taking of these drugs is sometimes offered as a defence, though it is just as illegal to drive a car when under the influence of a drug as when drunk.

The Abstaining Motorists' Association in Sweden⁴ has an impressively growing membership and the insurance companies now offer its members reduced rates having found that even a glass of beer on an empty stomach makes the average driver more prone to accidents. Our roads would be safer if all motorists noted this fact.

"GIVE US THE TOOLS"

On his installation last week as president of the Society of Medical Officers of Health, Dr J. M. Gibson, of Huddersfield, said that the foundations of the public health service have been undermined, and the society must indicate very clearly what tools and materials are wanted for its rebuilding. Unfortunately so much might be spent on the elaborate structure for treating disease that expenditure on prevention might be curtailed. Specialisation had increased to the point of having "57 varieties" of consultant but new houses were the primary need for health. The M.O.H. could not remain divorced from hospital work, and his voice should be heard on the regional board as well as on house committees and management committees. (The most essential qualification for a hospital superintendent, in Dr Gibson's opinion, is a medical training and sooner or later lay administration will have to be abandoned on grounds of both efficiency and economy.) The M.O.H. must have as much responsibility as possible in the running of isolation hospitals retaining his clinical contact—preferably as medical superintendent. He ought to control the admission and discharge of patients from tuberculosis sanatoria and bookings for admission to maternity homes should likewise be made through his department. He should co-ordinate the care of old people and the children's officer should operate as one of his team. Dr Gibson also felt that the supervision of milk at all stages of production and distribution should be restored to the M.O.H. he wanted preventive medicine more closely linked with industrial medical services and he urged that the supervision of children should be continued through adolescence, if not throughout adult life.

He added that believing in the justice of their claims, members of the public health service await with confidence the decision of the arbitration tribunal now considering the need for salaries sufficient to attract recruits to public health.

THE DANGEROUS PLACENTA

The diagnosis and treatment of placenta praevia was the subject of a crowded and lively meeting at the Royal Society of Medicine on Oct. 20. Mr John Stallworthy reported the results obtained by an Oxford team in which the radiologist, Dr Frank Reid, played a prominent part, the main features of his technique were the use of an aluminium filter to reveal soft parts and the application of gravity in positioning the patients. It was not suggested that radiography should or could replace clinical methods, but in expert hands it was an invaluable aid to diagnosis. In cases where the presenting part failed to engage, placenta praevia could often be confirmed or excluded without vaginal examination, and in antepartum haemorrhage X-rays might demonstrate the site of the placenta and enable the patient to be discharged. If the presenting part could enter the brim and act as a haemostat vaginal delivery was permissible. If not caesarean section was indicated. In a series of 250 cases there had been 1 maternal death (nasopharyngeal carcinoma), the uncorrected

foetal wastage had been 18%, and the incidence of caesarean section 40%.

Mr C. H. G. Macafee thought radiography of limited value here, clinical methods, excluding vaginal examination should suffice for diagnosis. Placenta praevia was most commonly posterior, but the importance of the forward displacement of the presenting part had been exaggerated. Placenta praevia had been demonstrated in 108 of 341 cases of antepartum haemorrhage admitted to the Royal Maternity Hospital, Belfast, in the years 1944-48. 50 had been delivered vaginally after artificial rupture of the membranes, and 58 had undergone caesarean section. There had been 1 maternal death (incompatible blood transfusion) and an uncorrected foetal wastage of 14%. Prof F. J. Browne congratulated the opening speakers on the excellence of their results, which he attributed partly to chemotherapy, to the increasing use of blood transfusion and caesarean section, and to the early transfer of cases by general practitioners.

Mr McIntosh Marshall remarked that both the opening speakers had vindicated his persistent emphasis on the importance of physical signs. Placenta praevia could very often be diagnosed from the history and abdominal palpation. Other speakers dwelt on the supreme importance of conservative methods of treatment, and spoke with feeling of the uncontrollable haemorrhage which might follow an injudicious vaginal examination. One and all agreed that radiography, however good, must not be allowed to displace clinical methods, and when Mr Stallworthy rose to explain that he shared this opinion complete harmony descended on the meeting.

THE DENTAL NURSE IN NEW ZEALAND

THE school dental nurses who for nearly thirty years have relieved New Zealand dentists of the routine dental treatment of school children have achieved a high standard of technical efficiency and meet a very real need. The British dental mission which visited New Zealand to study this system has submitted a report¹ which shows how wholeheartedly the scheme is supported by the dental profession, the education authorities and the public. Dental nurses receive a two year training with pay before going out to work in the standard type clinics which have been erected in school playgrounds. Each nurse assumes responsibility for not more than 500 children between the ages of 2½ and 16, her duties including the filling and extraction of deciduous and permanent teeth and instruction in oral hygiene. The enrolment of children below 7 years requires no more than the written consent of the parent, but after that age a child must first be made dentally fit by a private practitioner at the parent's expense, and the readmission of defaulters is subject to the same rigorous condition. The British mission makes no attempt to judge the suitability of the scheme for this country, but justly observes that if it were introduced, some modifications might be necessary and the fullest co-operation of the dental profession would be required.

THE INFECTIOUS TUBERCULOSIS

THE fabric of our social services, for all the work that has gone into its weaving is still marred by ragged gaps. For half a century or more we have known that tuberculosis is no less preventable than leprosy, yet it has still to be prevented. True, there is growing insistence on prompt and proper treatment of the disease, but this derives from knowledge of the beneficence of modern therapy rather than from any sturdy new determination to be done with the infection. The sources of food poisoning we assiduously track down and remove, the sources of tuberculosis we commonly leave in the general community because we have simply not decided that this shall not happen.

The London County Council has been trying for some time to arrange suitable accommodation for patients with open tuberculosis who are unlikely to benefit from sanatorium treatment and who have either an unsuitable home or no home at all. The common lodging houses of London are known to harbour at least 160 such people. For over two years the responsibility for these people has been in doubt, but the Ministry of Health has now ruled that this rests, not with the regional hospital boards, but with local health authorities, and according to a report by the council's health committee, the Minister 'contemplates the provision of

³ Daily Mirror, Aug. 30, 1950, p. 4.

in the past. But the awards are, after all, additional to competence, and if, like marriage, they are something of a lottery, they should, also like marriage, tend on the whole to reward the worthy. If a financial incentive is still useful in medicine, they provide it within the service, they introduce an element of flexibility into a system that might otherwise be distastefully rigid, and we know enough of those already made to say that some have gone to first rate men whose modesty has forbidden expectations.

In the House of Lords last week Lord MORAN, as chairman of the Awards Committee, described how the awards are allocated, and pointed out that they are an integral part of the remuneration of consultants—not something that could be removed quite easily either as an economy or because of inconvenience caused, for example, to the universities. The N.H.S. in England, Lord MORAN said, has at present only 56% of the specialist establishment which the Ministry of Health thinks it will ultimately need. "Medicine, like other professions and other industries, must appeal competitively for the man of promise," and he felt sure that "if it were not for these awards we should not compete successfully." With few exceptions, in his opinion, consultants are in favour of the awards scheme and would be shocked if it were withdrawn: they signed their contracts on the understanding that after they

reached the peak remuneration of £2750—perhaps at the age of 40—there would still be a chance of financial advancement, and deep discouragement and disquiet would be caused if the agreement were for any reason dishonoured before the scheme had even been tried.

"If the financial circumstances of the country, as once before, meant that it was necessary to make a percentage reduction in the salaries of every profession, then medicine would gladly bear its share, but to take a fraction of a single profession and to confiscate a considerable proportion of their income is, I think, hardly in accordance with the elements of justice."

We share Lord MORAN's view. We think it right that exceptionally able consultants should be able to earn fairly large incomes, without looking for them in private practice. We recognise that there are cogent objections to the new arrangement, and that it would have been far simpler to pay consultants as though they were Civil Servants, but we believe that an innovation of this potential value deserves full trial, and we should deplore any attempt to interfere with it soon after it has made its difficult start. With surtax at its present level, the experiment costs the nation little, and we retain our hope that in a few years, with such modifications as may be needed, the awards system will win general approval as a useful departure from precedent, applicable possibly in other branches of medicine and also in other professions.

Annotations

THE HARVEIAN ORATION

THE fresh light shed on Harvey's life and work by successive Harveian Orators inspires increasing admiration. It was only fitting that Sir Leonard Parsons, F.R.S., in his oration last week, should discuss the contribution made by Harvey and his contemporaries to pediatrics, with particular reference to that comparatively little known work, *De Generatione*. Thus, as the orator observed, contains a wonderful description of the development of the human embryo from the eighth week of intra uterine life onwards. It also suggests that rickets was so prevalent in England in the 17th century that children walked and talked much later than they do now—a hypothesis further supported in the writings of Shakespeare, who makes the Nurse exclaim with wonder of the three year old Juliet—

"For then she could stand alone, nay, by the rood,
She could have run and waddled all about."

Harvey is believed to have influenced Glisson in his decision to take up medicine, and so he can be given some indirect credit for Glisson's work *De Rachitide*, which appeared in 1650. Another close friend, it is thought, was Sir Thomas Browne, whose writings touched on rickets but whose principal contribution to pediatrics lay in the antenatal field, certain of his statements can almost be taken to anticipate the effects on the embryo of dietary deficiencies and infection in the mother. Finally, the orator turned to Sydenham and contrasted his restatement of the value of pure observation with Harvey's emphasis on experiment. It was Sydenham who first described rheumatic fever in detail—though without mentioning the state of the throat in this condition—and it was the combination of his and Harvey's methods which raised British medicine to its greatest heights.

CONFERENCE ON RADIATION HAZARDS

THE conference organised by the new Institute of Biology and the Atomic Scientists Association, with support from the British Association, at the Royal Institution on Oct. 20-21 opened with symposia on the biological effects of radiation and the protective measures used against any kind of harmful nuclear radiation. These prepared the way for the geneticists to discuss the hazards of radiation to the general population. Several speakers insisted that those who control the output and distribution of radioactive materials or other sources of dangerous radiation should be animated by a high sense of duty. In the geneticists' view, since experimental mutations caused by X rays are detrimental, if such mutations occurred in man and were maintained for many generations the prospects for the human race would be gloomy, some even said that man already has quite enough genes for natural selection to play on, and more would be an encumbrance or

worse. The last symposium, on atomic energy and the future, somewhat lightened the gloom by emphasising that there is no proof that deleterious mutants are produced in man by radiation, so we can take heart provided we also take precautions. In the final session there were strong expressions of opinion on the still greater hazards facing the scientist in the cloud of secrecy which is spreading over his work and which threatens his heritage of integrity and his traditional desire to reveal the truth. The atomic scientists were reminded that evil may arise from their studies. Without them the atomic bomb would not exist, they have thus become a menace to civilisation and suspect by the great body of the public. The plea behind these remarks was for action at the highest level to put an end to the prostitution of science.

ALCOHOL AND THE MOTORIST

CONVICTIONS are not easily obtained under section 15 of the Road Traffic Act, 1930, which lays down penalties for "Driving, or attempting to drive, or being in charge of a motor car on a road or other public place, while under the influence of drink or drugs to such an extent as to be incapable of having proper control." The driver's capability of having proper control has usually to be judged from the opinion of police and medical witnesses, and in borderline cases their evidence is often conflicting because the police describe the accused's condition when he was arrested, whereas the doctor does not examine him until he is charged, which may be some time later. Dr Gorsky¹ strongly disapproves of acrobatic tests for drunkenness, such as walking along a chalk line or repeating difficult phrases, which confuse the nervous and are sometimes remarkably well done by the drunken. Alcohol affects a man's car driving long before the stage of dysarthria and incoordination: the driver who faultlessly performs all the mechanical movements of driving may yet be dangerously defective in judgment, reaction time, and consideration for others, on which avoidance of accidents largely depends.

The alcohol content of the blood and urine, or of the breath, which is now being studied in America,² will reveal how much alcohol the driver has consumed, though delayed absorption may lower the findings in habitual drinkers, but the intoxication produced varies widely in different people and circumstances. Nevertheless, in Sweden the blood alcohol level is always estimated when motorists are charged with drunkenness or involved in an accident, and a fine follows automatically if the level is over 0.08%, while if it exceeds 0.15% the punishment is up to a year in gaol. In Denmark, too, even if the clinical examination is satisfactory, a blood level of 0.1% will earn the motorist 14-40 days imprisonment.

THE SUPPLY OF SPECIALISTS

From the opening speech Lord MORAN got the impression that what was wrong was that there were not enough doctors to go round. Speaking of the supply of specialists, of which he had expert knowledge as chairman of the Awards Committee, he said that shortage was certainly the fundamental factor. The Colonial Medical Service needed 1500 specialists and was about 200 short. The R.A.M.C. needed 455 and it had only 197—a further 157 known as graded specialists were really of junior registrar status. To second to the R.A.M.C. specialists from the N.H.S. was no good if there was a shortage in the N.H.S. The Ministry of Health aimed at ultimately having 7000 whole time specialists in the N.H.S. But in England and Wales there were only 5200 part time specialists and if part time was estimated at three quarters time this meant that only 56% of the Ministry's target were available. He believed that the fundamental task was to see that there were enough specialists for every service. Men would not undertake an intensive course of training spread over 14 years unless they were offered adequate material rewards. At present this was being done by the novel method of distinction awards, and Lord Moran did not believe that any Government would scrap this system without giving it a trial. One of the purposes of the N.H.S. was to upgrade backward hospitals, and this could only be done by some decentralisation of specialists. The distinction awards would help to make this possible by making men a little independent of private practice.

NEEDS AND REMEDIES—

Lord BOYD ORR supported integration of all medical services as an important and essential part of our preparations for defence. The new biological weapons as well as atomic bombs, would not discriminate between civilians and soldiers. Lord AMULREE was anxious that we should spread the high standard of British medicine among people in the Colonies by exchange visits of doctors. He also wanted to see many more patients brought from the Colonies to Great Britain for specialised and difficult forms of treatment.

Lord WEBB-JOHNSON reminded the Lords that he had raised the need for improved pay and conditions of service in the Forces nearly two years ago. After describing the disappointing answers he had received at intervals since he reaffirmed his belief that there was no basis for integration until the rates of pay were settled. He believed that secondment not only from the N.H.S. to the Forces and the Colonial Medical Service but in both directions would be of great value. Within the last few weeks the Colonial Office had arranged for superannuation rights to be carried on if a doctor entered the Colonial Medical Service. It should be possible for a doctor within twelve months of leaving the N.H.S. to be seconded from the N.H.S. to one of the other Services and in due course to return to his N.H.S. appointment.

The Marquess of SALISBURY said, that as chairman of a war-time committee of Ministers set up to allocate the supply of doctors between the Armed Services and the civilian population he had formed the opinion that there should be some permanent scheme to operate in peace as well as in war to ensure, without violent fluctuations, a fair flow of doctors where they are most needed.

GOVERNMENT REPLY

Lord SHEPHERD replying for the Government admitted that the Forces were short of 400 specialists and 100 general duty doctors. In the Colonial Service the shortage was 200—or 10%. These figures were serious but he thought they need not cause undue alarm provided the Government of the day and the medical profession were anxious about the situation. With better organisation and better conditions, he was sure, we could change the deficit, not into a surplus, but into a sufficiency. Was the deficit due to bad conditions in the Services or to shortage of doctors outside? In 1930, Lord Shepherd said the number of registered doctors was 54,637 of whom 9000 lived abroad. In 1940 the figures were 62,847 and 11,000 this year 77,730 and 12,000. But though there was an increase in the number of doctors was there really an increase upon which we could depend for feeding the Forces? We must remember that many women were now doctors and half of them did not practise. Again only the younger members of the profession were likely to be attracted into the Services. The older ones were already settled and unlikely to leave their families and practices save in an emergency. The large N.H.S. demands had also reduced the number of doctors available for the Services. These figures he suggested, showed that we must not think

how to transfer men and women from outside into the Forces or into the Colonial Empire but how to recruit more doctors.

According to an inquiry being made, at the request of the Minister of Health, there seemed to be a preponderance of students who wanted to be trained as specialists and not as general practitioners. This suggested that the encouragement offered to students to prefer specialist work was sufficient. Indeed the Minister of Health wished to use his influence and that of the hospital and university authorities to persuade some of these would be specialists to reconsider their position and to take early service in the Army as general medical men. The Government had also arranged that men might transfer from the N.H.S. into the other services at home or abroad without losing their pension rights or seniority status. Hospital authorities had lately been asked to encourage some members of their medical staffs to obtain experience in the Colonies or the Forces by a temporary transfer.

An interdepartmental committee, consisting of representatives of the Ministry of Defence and the Ministry of Health was considering the co-ordination of the medical services with the Forces and the Health Services. The Government were also considering the future of the Medical Priority Committee, the Central Medical War Committee, and the Committee of Reference. At any rate the integration of the Services had the blessing of the Government.

Turning to the question of payment, he said that it was now realised that after years of difficulty there must be a restrained movement both of wages and of salaries. The claim of the medical branches of the Services could be made not merely on grounds of the increased cost of living, but because it was right that men in the Forces should not be worse off than medical men in civil life or than men employed on general military occupations in the Forces. The Government were conscious that promises had been made before on this point. Though he could not yet make an announcement he understood that the Ministries concerned had pressed this point upon the Treasury, and he was informed that "the hope is not too large to entertain that this will be the last time that your Lordships are bothered about this particular claim. The circumstances were urgent and he was sure it would be in the interest of the country that this thorny problem should be settled satisfactorily once and for all."

In England Now

At school in the physics laboratory we were encouraged to believe that heat, light and sound are important. Those responsible for the new debating chamber of the Commons clearly share this view. In future our members of Parliament will legislate in a good light with cool heads and warm feet. Breathing the correct amount of suitably warmed air, they will hear without effort the lightest word of the most distant back bench.

The main electric lighting of the new chamber is provided by 150 glass panels in the ceiling which can be brought up gradually from nothing to full strength as daylight fades. Two air-conditioning plants circulate warmed air at a temperature which will vary with the number of occupants. On a division air is diverted from the chamber to reinforce the normal supply in the crowded lobbies. Beneath the green carpet, steel panel foot warmers have been embedded flush in the floor to offer a gentle warmth to the members' feet. The temperature of the chamber will usually be kept at about 67°F, or in summer, about 10°F below outside temperature. These adjustments will be made by an engineer from a control room below the chamber. To help him in his task of intelligent anticipation a 65 ft periscope and a loud speaker enable him to follow what is going on in the chamber.

Microphones hang at intervals from the galleries. One has even ventured on to the table before the Speaker. Small loud speakers—unobtrusive grilles in the woodwork between every two seats—reinforce natural speech but are set so low that they will not clash with natural speech, and those nearest to the microphone which is in use are automatically switched off. Members will sit on the traditional green leather benches, which are now cushioned with sponge rubber. The width of the seat and the slope of the back was settled after taking medical opinion.

Whatever the architects and the aesthetes may say about the tactful Gothic style of the new chamber, the members should certainly find it more comfortable than the old one.

hostels and night sanatoria by local health authorities as an essential part of the future development of the tuberculosis services." At present, however, he cannot approve the council's scheme for building a night sanatorium and industrial workshops on the site of St Peter's Hospital, Stepney¹, and in the face of this refusal the committee, which cannot obtain vacant hospital accommodation, proposes to seek his approval for the first of a series of hostels which would be opened in adapted premises and financed by money voted for other purposes. There are two special reasons for such action as this. One is that some of the homeless tuberculous, though possibly trained in sanatorium precautions, may be less likely than most to observe the prescribed routine. The second is that many in this group will be unfit for full employment—they may in fact be homeless for this reason—and these can claim in their own right, some thought from the community. If the rule of first things first is to prevail the committee will find the modest support it seeks.

SEBUM AND KERATIN

STUDIES of the surface skin fat, or sebum, and of keratin are throwing new light on the etiology and treatment of skin disorders. MacKenna and his colleagues² obtained sebum from the skin of normal men by immersing the forearm in acetone which was subsequently removed by distillation. In the residue they found about 5% of squalene (an unsaturated hydrocarbon, $C_{30}H_{50}$) and significant amounts of vitamin E, but no significant amounts of any other fat-soluble vitamin, of β carotene, or of ergosterol. They can give no decisive evidence that the squalene has any special metabolic rôle, but vitamin E, which is an anti oxidant, may help to retard the oxidation of unoxidised fatty acids and related compounds in the sebum. Anti oxidants may also be very important for keeping the skin flora within bounds, and the so called seborrhoeic disorders may prove to be due to qualitative abnormality of sebaceous secretion, or dyssebosis, rather than to excess secretion, or seborrhoea, which is observed chiefly in acne vulgaris.

Much uncertainty also exists regarding the chemical processes of keratin formation. Reducing agents, such as sulphur, have long been used for treating not only "seborrhoeic dermatoses" but also conditions of faulty keratinisation. The use of pyrogallol in psoriasis is an example. Reduction is probably an essential feature of keratin formation. On the ground that sodium *p* aminosalicylate inhibits the metabolism of the tubercle bacillus by increasing its oxygen demands, Thiers³ has administered this substance in conditions associated with dyskeratosis, such as psoriasis, pityriasis rubra pilaris, and lupus erythematosus. Usually the erythematous element was unaffected, but the rate of pathological keratosis was apparently lowered. The favourable effect of sodium *p* aminosalicylate seemed to be cancelled by ascorbic acid but enhanced by nicotinamide, when these were administered concurrently. To patients with lupus erythematosus Thiers gave 10 g of sodium *p* aminosalicylate by mouth and 0.5 g of nicotinamide intravenously each day. In two cases, one of which was of thirty years duration, both the erythema and the desquamation disappeared completely, and in a third these signs decreased. Thiers admits that the number of cases is small, but the idea behind the method may stimulate further studies of the biochemistry of the skin and its products.

PREPARING FOR GENERAL PRACTICE

THREE deans of American medical schools who visited this country early in the year were struck by the unpopularity of general practice as a career. In their report,⁴ they make the following pertinent comment: "Undoubtedly one development in British medical education which causes great concern has been exaggerated by the National Health Service Act. That is that almost all students and recently graduated physicians want to become specialists. Even before the Act the lot of the general practitioner in Britain was not too happy, and today it is demoralizing. We do not refer to overwork but rather to the fact that he seems destined to a routine life which does not offer the necessary facilities to practice good medicine and which fails utterly to offer the

professional incentives which lead to continued growth of the physician. If we really believe that the general practitioner is the 'backbone of medicine' then let us prepare him for the most difficult task in medicine. After our experience in England, we are confident that this is the most important job facing the medical schools of the United States during the next decade."

There are signs that the Americans are already studying the problem in their own country and taking steps to deal with it. Last year American students in 31 "classes" were asked about their plans.⁵ Of those questioned, 47.3% declared their intention of entering general practice, 31.1% wanted to specialise, and the remainder retained an open mind. The proportion wanting to specialise was higher among the senior than among the junior students, but the over all proportion of would be general practitioners was 14% higher than it had been three years before. This rather unexpected trend is associated with a growing recognition of the need to prepare students for general practice. Last year 42 of 79 American medical schools had courses designed to interest their students in this field of medicine, and had arranged to attach their students for varying periods to local practitioners, 15 teaching hospitals had established internships specifically designed for prospective G.P.s, and 12 were creating registrarships for the same purpose.

THE Wellcome Foundation have given the Royal Society of Medicine £80,000 to establish within the society a medical research library to be known as the Wellcome library.

Parliament

Medical Man-power

OPENING the debate in the House of Lords on St Luke's Day, Lord HADEN GUEST said that though he urged the greater integration of the National Health Service, the medical services of the Armed Forces and the Colonial Medical Service, he did not think that these services should be fused into one, for their traditions and functions were separate. But under present world conditions we must provide good medical services not only for the population of these islands and the Colonies but also for the Army, Navy, and Air Force. The N.H.S. had about 19,000 general practitioners, about 5500 consultants, and about 3500 senior hospital medical officers and senior registrars—a total of 28,000. The Armed Forces had about 2500 and the Colonial Medical Service about 1900. To secure an inflow of doctors into the Colonial Medical Service the Medical Priority Committee (of which Lord Haden Guest is chairman) had recommended that doctors who accepted Colonial Office posts in such places as Hong Kong and West Africa should be regarded as discharging their liability to military service.

In this country the Services could to some extent make up their deficit by employing civilian doctors. But this system had its drawbacks. The civilian doctor received higher rates of pay than the other officers in his unit perhaps even higher than the director of medical services of his Army formation. As a result no young man would apply for a short service commission when he could go out, qualify as a specialist, and come back at a higher rate of pay. The usual objections made to Service life, besides unfavourable pay, were that it cut a man off from his profession, limited his medical experience, and took him abroad. Then when he was between 50 and 60 it left him stranded with a smallish pension and nowhere to go. Much the same objections applied to the Colonial Medical Service. The remedy Lord Haden Guest declared, was to put the other Services on equality with the N.H.S. He believed that

Every doctor unless he deliberately opts out should from the time of his qualification and registration be put on an equal footing with every other doctor and should be eligible for the same pension and other rights on the terms and conditions which are applicable to the National Health Service.

He also suggested that a formal link should be created by the Ministry of Health between representatives of the medical branches of the Services in each command and the N.H.S. and university representatives in the area. If all were put on an equal footing the prospect of two years service with the Forces or six years in the Colonies, would change from a duty to be performed to an opportunity to be accepted.

It was tantalising of the Ministry to send me their fascinating *List of Proprietary Medicines Advertised Direct to the Public* only to tell me of therapeutic miracle workers that my N H S patients cannot enjoy. For this is a list in which Chaucer and Milton, Donne and Herrick, Bunyan and Swift, Keats and Gerard Manley Hopkins—to say nothing of James Joyce—might have collaborated. How Mr Ivor Brown would enjoy its rich assonances, its apt alliterations, its artful neologisms. How its anonymous author, after despatching his appendiceal after thoughts deleting 50 entries, must have thrilled at what remains. Even a compositor would wax lyrical over it.

Who would not babble of Bablets, and Blue Lion Fox Nuts (Shadforth's)—I like the bracketed Shadforth's, no ordinary undenominated blue lion fox nuts for my patient. Then there's Blinblow's Asthma Cure, the name a cure in itself. You can imagine the poor panting asthmatic at the chemist's counter, bubbling and blowing until—at last—he gets the whole name out in one triumphant gasp. Cured on the spot, I'll swear. De Witts Little Laxative Pills have a tactfully minimising sound, no need to be ashamed of asking the lady assistant for little ones. Grasshopper Ointment conjures up a vision of some serious soul rubbing it in while he studies the little grey books to rid himself of "the grasshopper mind." Nothing could be more Sunday school sounding than Infants' Friend, surely a tincture for the lambs of the flock, while for the hardened black sheep there are always Jordan's Gin Pills. There's Odds On Liniment for horsey devil may care characters, and the hard bitten worldling, disillusioned and taciturn, may find stern comfort in Shadforth's or Songo. For Christopher Robin there's Teddy-lax, and for diehard imperialists Union Jack Paste—by Gad, Sir! White lions (not to be confused with Blue) bring up the rear of the Noah's Ark procession, and for a last beneficence there's Omega Oil.

The list will be a godsend in prescribing for my private patients

* * *

A Scandinavian authority on Blood alcohol tests for motorists has sent me an extract from the *Daily Mirror* of Aug 30. "Enclosed," he says, "you will find the latest news about the investigation of intoxicated drivers in England, and I hope you will be pleased with the progress made." The extract is as follows:

THE FRIED EGG TEST GAVE HIM LICENCE BACK

A man accused of driving a car while under the influence of alcohol ate a fried egg at the police station in the morning after he was arrested; magistrates were told yesterday.

And that said Mr J H Glover was proof his client was sober. Doncaster magistrates restored the driving licence of the man who ate the egg—George Stevenson, 51, a Leeds traveller, who was convicted on February 14.

Mr Glover said: "It is often the subject of a music hall joke but for anyone who can eat a fried egg on the morning after they have experienced a surfeit of alcohol it is the acid test."

News

The report for 1949-50 by the management committee of the Executive Councils Association for England includes figures for the rate of payment to general practitioners participating in the N H S during the twelve months from April 1, 1949 to March 31, 1950. Payments totalled £37,999,463, and 1721 practitioners were receiving the fixed annual payment of £300. Among the 123 executive councils the capitation fee varied from 15s 6d-16s (2 councils) to 17s-17s 6d (16 councils). On Jan 1, 1950, a total of 16,698 principals and 947 assistants were in the service in England.

The University of Leeds has conferred the title of emeritus professor upon Dr M J Stewart on his retirement from the chair of pathology. Dr R E Coupland has been appointed lecturer in anatomy. Dr G Watkinson lecturer on medicine and Dr J A L Vaughan Jones part time lecturer in public health.

On Oct 18 the Blisset Hawkins medal of the Royal College of Physicians of London was presented to Sir Wilson Jameson for his services to public health.

On Thursday, Nov 16 at 5 P.M. Dr E R Cullinan will deliver the Bradshaw lecture at the college. He is to speak on the Clinical Interpretation of Jaundice.

On Tuesday, Oct 31 at 8 P.M. at the Royal Anthropological Institute, 21 Bedford Square, London W.C.1 Prof W E Le Gros Clark, F.R.S., and Mr L S B Leakey, PhD will speak on the Miocene Apes of Kenya.

On Monday, Nov 6 at 5 P.M. Prof R A Peters, F.R.S. will deliver the Cameron lecture of the University of Edinburgh. He has chosen as his subject Applications of Chemical Defence Research in Medicine.

In England and Wales notifications of poliomyelitis during the week ended Oct 14 were: paralytic 223 (241) non paralytic 85 (112), total 308 (353). The figures for the previous week are in parentheses. Total uncorrected notifications for 1950 up to and including the week under review are 7012. The corresponding figures for 1947, 1948 and 1949 were 7454, 1825, and 4478.

Sir Harry Platt is to deliver the Bradshaw lecture to the Royal College of Surgeons of England on Thursday, Nov 9, at 5 P.M. He has chosen as his subject *Diagnosis and Prognosis in Sarcoma of Bone*.

On Wednesday, Nov 1 at 5 P.M., Dr George Edwards will deliver the first Hewitt lecture to the Faculty of Anaesthetists of the Royal College of Surgeons. He is to speak on Frederick William Hewitt.

Prof H E Frisbie (California) will deliver a lecture on the Histopathology of Enamel Caries at Guy's Hospital Medical School, London S.E.1 on Tuesday, Nov 7 at 5.30 P.M.

Prof R J Kellar will deliver a lecture at University College Hospital Medical School, London W.C.1, on Friday, Nov 3 at 5 P.M. He is to speak on the Circulation in Pregnancy.

Mr Herbert Read, D.Litt., will deliver the Ernest Jones lecture to the British Psycho-analytical Society, at 1 Wimpole Street, London W.1, on Wednesday, Nov 15, at 8 P.M. He will speak on Psychoanalysis and the Problem of Aesthetic Values.

At a meeting of the Harrelian Society to be held at 26 Portland Place, London, W.1, on Wednesday, Nov 15 at 8.15 P.M. Lord Anlroco will speak on Towards a Healthy Old Age.

The Medical Defence Union's new offices at Tavistock House, South Tavistock Square, London W.C.1, were opened at a reception on Oct 20 when Mr Ivor Back, the president and members of the council received the guests. The rooms, which include a council chamber with fine oak furniture, provide excellent accommodation for the M.D.U.'s many and increasing activities.

In England and Wales the stillbirth and infant mortality rates during the third quarter of this year were the lowest on record for any quarter. According to provisional figures published by the Registrar General in his weekly return for the week ended Oct 14, the rates were: stillbirths 22.3 per 1000 total births and infant mortality 24 per 1000 related live births.

At the London Hospital dinner on Oct 19 Sir James Walton, presiding, said that when he was a student the case-mortality of acute appendicitis was over 90%. In his three months clerking every student looked after one or two cases of typhoid at times the hospital daily turned away 50 infants with summer diarrhoea, and a large proportion of operations were for excision of tuberculous joints or tuberculous glands of the neck. Today as one who had spent most of his life in removing organs he was most impressed by the progress of preventive medicine. Among the hospital staff the biggest change was the marvellous development of the team spirit, which was absent in his early days. He concluded with advice on the doctor's management of his years of retirement, and Sir Henry Tidy, proposing The Chairman, paid tribute to his undiminished zest for living.

A year ago Mr Wilson Hey, the Manchester surgeon, was fined for contravening the Dangerous Drugs Acts by supplying morphine to trained mountain rescue parties in accordance with the policy of the Mountain Rescue Committee (See *Lancet* 1949, II, 1228). Subsequently the Home Office authorised the issue of morphine by local practitioners to the supervisors of mountain first-aid posts. It seems that sometimes there has been difficulty in obtaining supplies in this way, and now the Home Office has agreed that Mr Wilson Hey or his deputy may issue this drug. Thus the practice followed up to a year ago has been officially accepted.

The state of civilisation of a community can be deduced from the way it looks after its lame ducks—and ducklings—said Prof Alan Moncrieff when he addressed the 62nd annual general meeting of the Invalid Children's Aid Association on Oct 17. Judged by these standards Great Britain emerged with credit. He continued especially since the Education Act of 1944. However many of the admirable facilities which might be provided for invalid children under existing legislation did not in fact materialise and there was scope for co-operation between voluntary bodies and local authorities in filling the gaps. Dr O D S Agassiz of Queen Mary's Hospital, Carshalton, observed that the problem of the invalid child presented three aspects—accommodation, education and training for an occupation. He pointed out that these children could be helped to live remarkably normal lives and told a story of a spastic child taking dictation from another who could not write. When they reached the words *sufferer from cerebral palsy*, the child ejaculated: But I'm not suffering.

Dr Peter Henderson of the Ministry of Health said that there were 8000 physically handicapped children among the total school population of 5 million. There were 74 special schools to cater for them, of which 55 were run by local education authorities. The eradication of rickets and osteomyelitis and the fall in the incidence of bone and joint tuberculosis had reduced the demand for special schools for the partially handicapped children. Prof W S Craig, of Liverpool, wound up the meeting with an appeal for £15,000 for the association's latest project—a holiday home for invalid children. It had previously been disclosed by the treasurer that the association has an overdraft of about £12,000 and the excess of expenditure over income last year was £3000.

CORRIGENDA *Effects of Cortisone in the Rheumatic Diseases*—In the first of the plans for administering Cortisone or A.C.T.H. enumerated in our report last week (p. 483) of Dr Hench's lecture each course lasts for about 3-6 weeks. With administration of these substances the serum protein and the hemoglobin tend to become normal. The substances that have been investigated as possible alternatives to cortisone include 21-acetoxy pregnenolone, delta 5 pregnenolone and desoxycorticosterone with or without ascorbic acid.

Anti-histamine Drugs and the Blood—Hydrochloride in the eighth line of last week's annotation refers to triphenylamine hydrochloride.

HAVING been allowed to run its damaging course for nearly six months, the illness of the London printing industry has now passed its second crisis and seems to be ending. In expressing once more our deep regret at being prevented from meeting so many obligations in the past few weeks, we must also thank readers, contributors, and advertisers for the understanding they have shown. We look forward to rapid recovery of full function.

The Kidney and Cardiac Œdema

CARDIAC Œdema cannot be satisfactorily explained by filtration of fluid from capillaries subjected to a slight rise in internal pressure. ALTSHULE¹ pointed out that the extent of cardiac Œdema was in no way related to the height of venous pressure, while RAY and BURCH² found that the Œdema which followed ligation of the inferior vena cava tended to clear up despite a sustained rise in venous pressure in the feet. Such factual observations have led to a search for some other factor, and attention has been diverted to the kidney.

BORST³ in 1938 remarked that in the circulatory collapse which follows hæmatemesis the kidney retains salt with such avidity that infused saline may raise the plasma-chloride as high as 20% above normal. Severe hæmatemesis is known to reduce the kidney blood flow⁴. MERRILL⁵ showed that in cardiac failure, too, the kidney blood flow is reduced, often very grossly, and this reduction is associated with excessive retention of sodium by the kidney. MOKOTOFF and his associates⁶ thought that the decreased glomerular filtration accompanying this diminished blood flow might account completely for the decreased salt elimination. FEJFAR and BROD⁷ support Mokotoff's hypothesis, citing the idea put forward by WESSON and his colleagues⁸ that, while 85% of salt absorption takes place in the proximal tubules, reabsorption of the remainder is subject to quantitative regulation in the distal tubules. In the distal tubule-sodium chloride is absorbed at a fixed maximal rate; reabsorption increases with slow passage of a small amount of glomerular filtrate and decreases when the fluid being filtered is larger in quantity and therefore moves faster. LOWE⁹ suggests that the salt retention associated with cardiac Œdema should be subdivided into two groups. First there are the cases in which salt excretion continues on a low dietary salt intake, so that by dietetic means alone Œdema may be slowly eliminated. In the second group mercurial diuretics are necessary to reduce salt and water reabsorption by the kidney and thus to get rid of Œdema. In cases belonging to this second group LOWE found an excessive amount of antidiuretic hormone in the urine. BERCU et al.¹⁰ have also noted antidiuretic effects following the injection into hydrated dogs of urine from patients with cardiac failure, but they thought that these effects were not due to a substance with the characteristics of 'Pitressin'. It would certainly appear that diminished renal blood flow

and glomerular filtration in heart failure do not, by themselves, account for the decreased salt elimination; hormonal factors are almost certainly involved. BORST's observations of excessive salt retention³ can be explained only by some profound alteration in the reabsorptive activity of the tubule cells.

The mechanisms of reduced kidney blood flow and other changes in kidney function in heart failure are still mysterious. BROD and FEJFAR¹¹ have made a valiant effort to solve the problem by observing nocturnal changes in cardiac output and kidney function, both in normals and in patients with heart failure. It is known that at some stages of cardiac failure diuresis may take place during the night, but BROD and FEJFAR were unfortunate in that very few of their patients reacted in this way. When diuresis did occur it was usually accompanied by an increase in kidney blood flow which simply indicated reversal of the daytime diversion of blood from the kidney to other tissues. Fluctuations in kidney blood flow could not, however, be correlated in any way with changes in cardiac output, right auricular pressure, or other hemodynamic measurements made at the same time. There was no relation between salt retention and venous pressure, such as might have been expected from BORST's¹² suggestion that salt retention contributes to the venous pressure rise in cardiac failure. Reduction in renal blood flow and in elimination of salt is not confined to cardiac failure; it may be found in normal subjects during exercise^{13,14}. It has been suggested that in cardiac reduced kidney blood flow may be determined by venous congestion,¹⁵ but KATZ and his colleagues¹⁶ have now shown that this effect is shortlived; in dogs, after a few days of sustained chronic renal congestion kidney function has returned to normal in respect of water and salt absorption. Since there does seem to be a rough relation between reduction of renal blood-flow and the degree of clinical cardiac failure¹¹ it might be thought that anoxia contributed to these renal reactions. AAS and BLEGEN¹⁷, however, have shown that both in normal subjects and in patients with cardiac failure kidney blood flow is increased by inhalation of 9.5% oxygen, but this of course, may not reproduce exactly the anoxic mechanisms in heart-failure. It is difficult to avoid the teleological suggestion that the kidney blood flow is reduced by 'splanchnic vasoconstriction' when a generally inadequate cardiac output is partitioned in the interests of other more vital organs.

The importance of the kidney in cardiac failure is established. Its blood flow may be grossly impaired, and almost certainly further factors—humoral or hormonal—exaggerate the activity of tubule cells in the retention of salt. The place of pituitary and suprarenal cortical hormones in this picture is still ill defined. Mercurial diuretics act primarily by depressing salt and water retention by the kidney. PUGH and WYNDHAM¹ have demonstrated secondary beneficial consequences of

into clinical medicine—not yet as a form of treatment (for he is careful to deny it this status) but as a means of modifying disease processes many of which were previously regarded as unrelated. The medical world can be grateful for the care with which the Mayo Clinic work has begun and has been continued, but not even Dr Hensch's wise caution can obscure what seems to be the dawn of another new day in therapeutics. To this sunrise in the Middle West, investigators elsewhere have of course contributed, and all who study steroid hormones will be glad to see Reichstein's name joined with those of Hensch and Kendall. Professor of pharmaceutical chemistry at Basle, he has devoted most of his life to steroid substances, and cortisone was among the 28 hormone substances he is said to have isolated from the suprarenal gland in four years intensive research. His investigations on the steroids of plants have enabled him to indicate possible means of converting them into cortisone.

PAIN IN MYOCARDIAL INFARCTION

WITH infarction of the heart, diagnosis has far outstripped prognosis. An attempt to put prognosis on a surer footing has therefore been made by Behrmann and his colleagues¹ who have studied the relation between pain and mortality in 150 cases among which the mortality rate during the first four weeks was 35%. They found that the mortality increased with the duration of pain among patients whose pain lasted less than 5 hours the rate was 11%, but it rose to 34% when the pain lasted 5–25 hours and to 39% with pain for 25–120 hours. As to the site of pain, among the 44 patients in whom it was confined to the anterior trunk the mortality rate was 59% whereas among the 95 with pain radiating beyond the anterior trunk the rate was only 18%. This rather surprising observation—that patients with pain confined to the anterior trunk are more likely to succumb—has been recorded previously², and Behrmann and his associates suggest that in patients with a large infarct which proves fatal, profound shock may cause dulling of the sensorium and a diminution in the 'overflow phenomena of impulses which are apparently a part of the picture of referred pain.

This study demonstrates once again the variability in the mode of onset—a feature further underlined by Stein³ in an account of 7 cases of myocardial infarction where chest pain was present only on exertion. The pain pattern was characteristic of angina pectoris and it was only through serial electrocardiograms that the correct diagnosis was reached. In most of these cases however, there were clinical features suggesting infarction. Thus, often the pain was severe, it began, quite suddenly to come on with much less exertion than originally, and the response to nitroglycerin became less satisfactory. One of Stein's cases indicates that in a young adult anything like severe angina pectoris should arouse suspicion of infarction.

LIGHTENING THE N.H.S. DRUG BILL

DOCTORS in general practice who have tried to obey the Ministry's behests by prescribing *National Formulary* alternatives for proprietary or branded preparations are finding that some are unobtainable and likely to remain so for years because only the owner of the proprietary rights may make them. In other cases the wholesale chemists are producing the *N.F.* preparation under licence from the patentees, or they are buying the finished proprietary product from the makers and preparing it in accordance with *N.F.* requirements. Thus prescribing drugs in their non-proprietary forms does not always save the Treasury much money, however beneficial it may be to the prescriber's soul.

Another way in which money might be saved with no loss of efficiency, is by reducing the waste of unused medicines. Thousands of bedroom and bathroom cupboards—many of them in doctors' houses—are bulging with half-empty bottles and boxes labelled 'The Mixture' or 'The Tablets' with the usual personal instructions about dosage. As a rule nobody can be certain what these medicines are or for what they were originally intended, so they can seldom be used again. In the end at an extraspecial spring-cleaning a move, or some more dismal occasion, they will be cast into the dustbin, or the bottles (unwashed) will be offered to the local pharmacist. The uninformative labelling is based on the

traditional view that it is no business of the patient what he is taking—scoffers even call this the cornerstone of therapeutics—though nowadays when the doctor usually hands the patient his prescriptions, only bad handwriting and natural inertia prevent his reading them. Continental pharmacists must copy the prescription in full on to the label of every medicament they dispense. If this practice was adopted here it would add considerably to the already heavy demand on pharmacists, but it would make it possible for household stocks of tablets, lozenges and even standard mixtures to be used if the need for which they were ordered arose once more. And it would reduce loss of time and temper when a new patient produces the remains of "what the other doctor ordered."

That the nation's medicine bill is excessive was again emphasised last week by Sir John Charles,¹ chief medical officer of the Ministry of Health, when he addressed the annual meeting of the Executive Councils Association of England. In the twelve months up to the last day of June, 211 million prescriptions were made out, and during the first six months of the year the average cost was 3s 1½d. It is difficult he declared, to believe that medicine drinking on this scale is of even temporary benefit to the nation's health. "Do we really need to breed a new race of three bottle men and women?" Steps are being taken, he said, to help doctors to discourage the taking of medicines as a habit.

SUPPLIES OF CORTISONE AND THE NEW ANTIBIOTICS

IN a written answer to a parliamentary question, the Minister of Health has announced that limited quantities of Cortisone are being imported for use in hospitals in this country, and that arrangements for production here will be considered as soon as possible. The amount produced must depend, however, on the supply of the essential raw material (ox bile) for which no substitute is likely to be found in the immediate future. Aureomycin Mr Bevan said, is already being imported, and the import of Terramycin will be considered if the need arises.

Mr Herbert Morrison who as Lord President of the Council is the Minister responsible for the Medical Research Council, stated that an extensive programme of co-ordinated research on cortisone and related substances is being carried out by the council. The provision of cortisone for the routine treatment of patients is, of course, outside the council's province, but he was informed that more research was necessary before the drug could be safely recommended for general use in rheumatoid arthritis.

SYNERGISM AND ANTAGONISM OF ANTIBACTERIAL SUBSTANCES

A FEW years ago Ungar² and Bigger³ showed that two antibacterial substances might act synergistically, on bacteria in culture media or serum. Ungar showed that the inhibitory effect of penicillin on staphylococci and streptococci was at least doubled by the presence of sulphapyridine in a concentration which per se was insufficient to exert any influence on the organisms. Bigger found that the presence of sulphathiazole in culture media and serum greatly increased the dilution at which penicillin inhibited staphylococci. Clinically there was some evidence that in pneumococcal pneumonia penicillin and sulphadiazine together were more effective than sulphadiazine alone.⁴ Bigger⁵ later investigated the activity of six antibacterial substances—sulphathiazole, penicillin, streptomycin, chloramphenicol, boric acid and p-aminosalicylic acid—in pairs on *Bact. coli* in a synthetic medium. Thirty combinations of two of these substances are possible and in all but five of these the two components acted synergistically, there was marked antagonism between boric acid and sulphathiazole and between boric acid and penicillin. Antagonism also exists between penicillin and succinylsulphathiazole⁶ and between penicillin and chloramphenicol.⁷ Spicer⁸ has investigated the action of five antibiotics—Aureomycin, chloramphenicol, streptomycin, penicillin, and Bacitracin—in pairs on a number of organisms. When the bacterial strain was sensitive to each of the pair the

mercurial diuresis on the heart output and venous pressure in heart failure, and mercurial diuretics, combined with low salt intake, thus assume a new importance in the management of the cardiac invalid. One of the many unanswered questions is why mercurial diuretics are phenomenally successful in some cases but fail miserably in others.

The N H S Through American Eyes

THE advertising campaign launched by the American Medical Association on Oct 8 marks the climax of a "national education program" intended to mobilise public opinion against the compulsory health insurance proposals now before Congress. This appeal to the American people through the press and over the radio was expected to cost the A M A about \$1,100,000, obtained by a levy of \$25 on every member of the association, but its total cost was very much greater, and the value of the advertising space provided by banks, insurance companies, drug stores, and other interested concerns has been estimated at \$19 million.¹ The object of the campaign is twofold. It is designed to make the public "health insurance conscious" by extolling the virtues of voluntary schemes, and simultaneously to "alert the American people to the danger of socialised medicine and to the threatening trend towards state socialism in the U S A".²

Naturally enough, a great deal is being said in America about the condition of British medicine, whose less satisfactory features are held to be the result of carrying compulsory health insurance to its logical conclusion. A delegation of the A M A which visited the United Kingdom last year³ attribute "the decay of medical practice in England" partly to National Health Insurance but more particularly, it seems, to the National Health Service Act. After reviewing the events which led up to the inauguration of the service, and surveying its "cumbersome" administrative machinery, the delegation proceed to examine its three main sections—hospital, public health, and general medical.

The British specialist is said to be working short hours for good money but to be paying for this privilege with his freedom and to be "as surely chained to his post as though he were bound by visible shackles". None the less this same specialist is in the habit of leaving an outpatient session as soon as his time is up, regardless of the number of patients waiting to see him. Our hospitals are handicapped by chronic overcrowding, their efficiency is decreased (*sic*) by an occupancy rate of 90-95%, and they are being inundated with minor cases which make them unable to care for patients who are seriously ill. Further, their running costs are stated to be excessively high, and the visitors found an independent hospital which operated at about two thirds the cost of a similar nationalised one. In general, the quality of hospital work is suffering and there is an increasing tendency to substitute laboratory investigations for clinical observation. Turning to the local health services, the delegation remark on the breakdown of school dentistry, and on the multiplicity of agencies concerned with maternity and child welfare. The ambulance and car services, while admirable in spirit, are being abused by all concerned, and thousands of patients, with attendants, are being "hailed around all parts of England". The tuberculosis services have suffered from the Act, and "5000 sanatorium beds and hospital beds have become unavailable because of lack of funds and personnel". Finally, as might be expected, the delegation were particularly impressed by the plight of the general practitioner. They found him trying to cope with more

patients than he could treat satisfactorily, and consequently referring more and more cases to the hospitals from which he himself was virtually excluded. The report continues:

"The general practitioner in Great Britain as we observed him is no longer a free, independent professional person. He finds himself sharply circumscribed in function, in influence and in outlook. His work tends to become more superficial as he is increasingly concerned with clerical and technical trivialities. The correction of present defects will depend on a reappraisal of the function of the family doctor and his reestablishment as the backbone of medical service to the population at large."

Commenting on the health service as a whole, the delegation take the view that it is designed to establish "not a better system of medical care, but a better controlled one". In so doing it has widened the gap between specialist and general practitioner, has aggravated the already great geographical inequality of distribution of doctors, and has added greatly to the cost of medical care. The middle income group, who were accustomed to paying their way, have benefited, but the low income group received as good or better medical care before the Act. All in all, the concept of medical care without direct payment by the consumer is held to be fundamentally unsound.

The opinions of these experienced American observers are not to be lightly dismissed, and some of them are of course widely shared by doctors in this country. At the same time, we must remember that we are being measured against the standards of the richest country in the world. It is true, as the Americans are not slow to point out, that the cost of our nationalised service has far exceeded the estimates, yet even today the annual cost is only about £9 per capita, whereas the average annual expenditure on medical care in the U S A is reported to be about \$70 per person—equivalent to £25 at the present rate of exchange (These figures are stated to represent 4% and 4.9% respectively of the national incomes in the two countries). All agree that the general practitioner's work suffers from the inflated lists which are still common, but we know of no evidence that overcrowding caused by the N H S is leading to a fall in the standards of medical care in the hospitals, or that consultants are tending to leave "on the dot" because they are paid for sessions of so many hours. Many of the bad points of our medical services—and we know that they are numerous—have been developing for a generation and cannot fairly be put down to the National Health Service Act, which, if it has not halted the trend, has certainly not accelerated it. The American delegation observe:

"The system that prevails in England today is certainly not all bad, but most of its virtues are those of the medical social service that existed before the Act". We should prefer to say that the system is certainly not all good, but that many of its faults are those of the medical social services that existed before the Act.

Annotations

THE NOBEL PRIZEMEN

THE 1950 Nobel prize for medicine goes to Dr Philip S Hench, Prof Edward C Kendall, and Prof Tadeus Reichstein, "for their discoveries concerning the suprarenal cortex hormones, their structures and biological effects". Professor Kendall, who is a true pioneer of biochemistry, produced some thirty years ago from several tons of thyroid gland, a few milligrammes of crystalline thyroxine, thus bringing the thyroid principle from the nebulous and indeterminate land of animal extracts into the realm of pure organic chemistry. Long years' research on suprarenal hormones led to the isolation in 1935, among other chemically pure substances, of Compound E or "Cortisone". To Kendall's friend Dr Hench, of the Mayo Clinic, goes the credit for introducing cortisone

Medical Societies

ROYAL SOCIETY OF MEDICINE

Medical Education

At a meeting of the section of medicine on Oct. 24, with Dr CHARLES E. LAKIN, the president, in the chair, Mr ROBERT BIRLEY, headmaster of Eton College expressed strong dissatisfaction with the 1st M.B. examination. It had, he said, a great influence on secondary education, on the selection of doctors, and on the medical profession itself. It set a great problem to school authorities, and whenever two or three headmasters were gathered together it was on the cards that they were discussing medical education. References to the 1st M.B. in the B.M.A. report on the medical curriculum, with whose views he was wholly in agreement, were almost too optimistic, for at the moment matters were getting worse rather than better. Mr Birley was strongly of the opinion that boys and girls should have a more general and less specialised education, but the inevitable influence of 1st M.B. was in the opposite direction. It was a source of amazement to him that in 1948 only about 13% of external candidates for the London University 1st M.B. passed the examination¹ there must be something very wrong either with the examination or with the candidates. It might appear to be impossible to say for certain which was at fault, but it was significant that of 41 boys and girls carefully selected for admission by University College, London, from some 300 candidates, only 23 subsequently passed their 1st M.B. and so qualified for admission. This cast grave doubt on the merits of the examination which nevertheless was a major factor in deciding who were to be the country's doctors in the future.

Mr Birley then turned his attention to the syllabus, which he thought was getting out of hand. The examination put a premium on the mastery and memory of facts. Historically, it was a university examination, but there was an increasing tendency for it to be taken at school. At Cambridge, for instance some colleges now insisted that all four parts be taken before going up, others merely indicated that this was preferable. The university medical faculty had been mainly responsible for this by abandoning all premedical instruction. Further figures from University College, London, showed that of 41 students for the 2nd M.B., 18 had taken two years, 19 three years and 4 four years from school certificate to obtain 1st M.B.¹ The general effect of the examination had been that school certificate was taken earlier and earlier—it was not the only factor involved in this general tendency—and that the teaching of subjects other than those needed for the examination was restricted. The great question was whether a boy should take 1st M.B. late (i.e., in whole or the greater part at the university) and have a wider general education or whether he should take it early at the expense of other subjects. Economic pressure worked in favour of the latter solution but Mr Birley was strongly in favour of the former, and he cited the arrangements at the Berlin Charlottenburg Technical University where all students spent their first year on general studies with the consequent necessity of an extra year at the university as an example of how boldly this problem was being tackled abroad.

THE CURRICULUM

Sir BENRY COHEN pointed out that the 1886 Medical Act had laid down that the standard of proficiency demanded in the qualifying examination should be sufficient to guarantee the possession of the knowledge and skill requisite for the efficient practice of medicine surgery and midwifery. At that time with the limited medical knowledge that existed, the curriculum fulfilled this purpose. Now the enormous expansion of medical knowledge made it necessary to restate the aims of the curriculum. Its purpose must be to show the student the scope and potentialities of medicine, to equip him with sound basic principles and indispensable techniques, and to give him resourcefulness and initiative. The general structure of the curriculum should, however, be retained. He agreed that the 1st M.B. examination was at present unsatisfactory, and he suggested in the interests of general culture that when two of its subjects had been taken at school the remaining subject should be studied during the first university year at the same time the student should be allowed to attend without fee any other courses he chose in the university. This was the practice in Liverpool. The

preclinical course should teach the normal structure and function, including normal psychology, of human beings, and should also impress on the student that he was a member of a family and of society. Continuity of the preclinical and clinical years was vital, and the elimination of the concept of disease entities in favour of 'departures from normal structure and function and their causes' would promote such continuity. Basic principles were more important than factual information though of little value without practical illustrations. As an example of general principles, Sir Henry remarked that the intensity of symptoms is proportional to the rate of pathological change and enlarged on this theme. It must always be remembered that the curriculum could never be final, there must be continual adjustment and a flexibility suited to the teacher as well as the taught. Students should be encouraged to question authority and to study the meaning of the words used by their teachers—words which so often were a cloak for ignorance. The teachers for their part must never forget the importance of intellectual honesty and must emphasise the human side of medicine throughout the training. The central aim of the curriculum was to prevent the practitioner from being taken by surprise.

GENERAL PRACTICE

Dr G. O. BARBER recalled the medical education he had received twenty years ago and paid tribute to the teachers who had given him a sound knowledge of medicine and surgery. None the less, he and his contemporaries had met great and unexpected difficulties when they tried to adapt their hospital training to general practice. Why should this be so? What were the differences between hospital medicine and general practice? They were, firstly, that a general practitioner had to look after the whole patient in his environment, secondly, that he had to do so without the facilities of a hospital, and, thirdly, that his cases were unselected and he must constantly be on the alert to distinguish major from minor disorders. There were two diametrically opposed ways of providing a community with medical care. It might be provided through large hospitals with all their facilities or it might take the form of care in the patient's own home. Dr Barber believed in the latter arrangement and held that the general practitioner should be the instrument of its realisation.

Turning to medical education he observed that all teaching could take the form of dogmatic instruction or of practical demonstration. The second was the accepted scientific method. Twenty years ago he and his generation had been turned out into general practice to sink or swim, and there was no doubt that patients had suffered. The young man of today must be guided into general practice, and this was in fact being done at one of the London hospitals where for fifteen years an attempt had been made to prepare the student for this work. The course—for such it was—comprised a series of talks by a practitioner on everyday problems and on the common ailments which form 90% of the work. Visits to a practice in action to meet the dispenser, district nurse, health visitor, and other auxiliary workers, and a film strip of daily work in general practice. Students were also invited to stay a few days on the premises and accompany the practitioner on his rounds and in his surgery. This course was well attended and was meeting a very real need.

From Letters to the Editor

Transvesical Prostatectomy—The operation of transvesical prostatectomy described by Mr Lee in your issue of Sept. 23 is essentially that first described by Thomson Walker in 1928, except for the primary closure of the bladder which, as Mr Lee says, is now possible because of antibiotics rather than improvements in technique.

As he points out one of the major difficulties of the operation is the control of hæmorrhage. In a transvesical operation hæmorrhage is most readily controlled by the technique originally described by Wilson Hey and later modified by the Liverpool school (This technique has been admirably described by Stock (*Brit J Urol* 1947 19, 200)). By this method it is possible to obtain an excellent view of the whole prostatic fossa and to pick up and either tie or diathermy all bleeding points under direct vision, thus eliminating all need for gelatin sponge or other hæmostatic agent.

In retropubic prostatectomy Millin has controlled hæmorrhage by injecting under the prostatic capsule 0.5 ml. of adrenalin in 20 ml. of 1% procaine. I have found that

effect of the two together was either additive or synergistic. When an antibiotic to which a bacterial strain was only moderately sensitive was combined with one of high activity the action of the latter was either impeded or was the same as if it had been used alone.

The synergistic effect of two antibacterial substances is readily explained. If both interfere at the same stage in a metabolic cycle within the organism, their combined effects may be expected to be additive. If, however, their mode of attack on the organism is different, the organisms surviving the action of one become exposed to that of the second, so that the two antibiotics act synergistically. Antagonism between two antibacterial substances is not so easily accounted for. One possible explanation is that the first produces some change in the cellular structure or metabolic processes of the organism as a result of which the second is either prevented from penetrating the cell, or having done so is unable to exert its usual action.

In practice two antibacterial substances might more often be administered together. This delays the appearance of resistant strains, and favourable results have already been reported from treating tuberculosis with streptomycin and *p*-aminosalicylic acid together, and subacute bacterial endocarditis with penicillin and streptomycin together. There is some evidence, too, that a combination of sulphonamides, penicillin, and streptomycin controls *Haemophilus influenzae* better than any of these agents alone.⁹

PRACTITIONERS' LISTS

THE dispute over the remuneration of general practitioners¹⁰ is closely linked with the question of how many patients a practitioner may have in the N.H.S. In his presidential address on Oct. 26 to the Executive Councils' Association of England, Dr N. E. Waterfield urged that "in the great majority of cases satisfactory service cannot be given, or the objects of the Health Service attained, with lists of more than 3000." The following reasons, he said, were given in favour of keeping the maximum at 4000.

1 Under National Health Insurance a practitioner might have under his care a good many more than 4000 when dependants were added to the maximum of 2500 panel patients.

2 During the late war many doctors had as many as 6000 patients and usually these doctors fulfilled their obligations.

3 Today patients are apparently satisfied with the treatment they get from doctors with large lists and those to whom a transfer is suggested immediately make an outcry.

4 Limitation of lists means limitation of free choice of doctor.

5 With the existing capitation rate a doctor cannot make a sufficient income without a list in the neighbourhood of the maximum—unless he has other sources of income.

Against this, methods of diagnosis and treatment are now increasingly elaborate, and arrangements for radiological and pathological examinations and for consultations with specialist lists occupy much more time than before the appointed day. Furthermore, Dr Waterfield continued, if the new service is to be a real health service, the practitioner must educate the public about health, but obviously with 30–40 people attending morning and evening surgeries and about 20–30 visits a day—which a list of 4000 probably entails—little time can be given to education. Also the doctor must have time for reading and attending medical meetings, and for relaxation, amusement, and exercise.

How is a reduction to be achieved? If the maximum size of lists were reduced practitioners could justly demand that incomes should be maintained by increasing the capitation fee. Without actually imposing a new limit, large lists could be discouraged by heavily loading the fee for the first thousand patients, but unless extra money were added to the remuneration pool the cost would fall on those who now have big lists. Loading after this fashion would bring some, though probably not enough, relief to those practitioners—mostly in residential areas—who are suffering hardship. Two months ago we suggested that doctors might be attracted to the urban underdoctored areas by grants from the Special Inducement Fund¹¹ and Dr Waterfield proposes that those who are in distress might be helped to transfer by a capital payment or an interest free loan. This would enable them to earn a reasonable living and would make for a more rational distribution of medical manpower. But for both the practitioners and their families evacuation of their chosen places would often be a grim business.

TUBERCULOUS PLEURAL EFFUSION

PLEURISY with effusion in patients under 40 is almost always tuberculous, but it used to be looked on as a mild and benign manifestation. Sibley's¹ study of 200 cases in a Canadian sanatorium suggests that these effusions should be taken more seriously and that many are associated with hæmatogenous spread. In 29 of the patients parenchymal lesions of the lung had preceded the effusion, 92 were found to have pulmonary lesions either at the time of their effusion or from a month to seven years later, and 10 subsequently developed clinically recognisable tuberculosis in other organs without involvement of the lungs, in addition, 37 patients developed lesions of hæmatogenous origin, the commonest sites being the genito-urinary tract, spine, peritoneum, and meninges.

Tubercle bacilli are rarely found in films and still more rarely cultured from the small amount of pleural fluid usually examined. But Barnwell² pointed out that by culturing a large volume of fluid, up to 500 ml, tubercle bacilli can be detected in about 70% of effusions from young people. Cytological examination may also help in diagnosis and should always be included. Lymphocytes usually predominate in tuberculous fluids, though a few show a leucocytosis in the early stages. MacMurray and colleagues³ note that fluids with over 5% of eosinophils in their cell-count are sometimes associated with the late stages of tuberculosis but are never one of its early manifestations. Schwartz and Broadbent⁴ aspirated fluid as soon as it was discovered in 7 patients with artificial pneumothorax, and 6 of the fluids contained 64–90% eosinophils. Eosinophilia may also be found in the pleural fluid in cases of lobar pneumonia, typhoid fever, asthma, Löeffler's syndrome, neoplasm of the lung, Bright's disease, and other conditions, but it should always raise a suspicion of tuberculosis. Tuberculous effusions mostly occur in patients with a high sensitivity to tuberculo protein, so a negative tuberculin test will virtually exclude tuberculosis except in the extremely ill. A positive test, on the other hand will not prove that the effusion is tuberculous, but will call for a full bacteriological and cytological examination.

DECISION POSTPONED

DELAYS outside the control both of the Government and of the General Medical Services Committee have prevented the collection of data required for reconsidering the remuneration of general practitioners. Accordingly the Annual Conference of Local Medical Committees last week recommended a further three months postponement of the decision whether practitioners should leave the N.H.S. The special conference will be called as soon as the information is available, or next March whichever is the earlier. It was generally agreed that if practitioners resign as a body from the service their withdrawal will not be effective unless they withhold certificates from patients wanting them for claiming National Insurance benefits.

Dr Brock Chisholm, director-general of the World Health Organisation who has been lecturing in the United Kingdom said at a press conference last week that W.H.O. is a technical body which wages war on disease, he found it hard to justify pacifism on the part of any country in this common cause. There has been a great increase in public interest in all United Nations agencies since the outbreak of the Korean war and five public health teams headed by Lieut Colonel Walter Crichton M.B. have already been sent to Korea to advise on urgent problems of sanitation and on long term reconstruction.

The centenary celebrations of Friern Hospital on Oct. 27 enabled visitors to obtain an impression both of the hospital's history and of its present activities. The austere exterior of the buildings has become increasingly misleading as the interior has been renewed and improved in the spirit of modern hospital care. Today as Lady Archibald, chairman of the hospital management committee, pointed out, Friern is a modern hospital just as it was 100 years ago when its foundation marked the transition from the old to the new attitude toward mental illness. Mr Arthur Blenkinsop, parliamentary secretary to the Ministry of Health congratulated the hospital upon its very high discharge rate. He said that over a quarter of all loss of work is due to mental disturbance and that 48% of the hospital beds in the country are devoted to these illnesses. Mr Fred Messer M.P. chairman of the North West Metropolitan Regional Hospital Board remarked that the ambition of a mental hospital must be to enable its inmates to enjoy life to the fullest measure of which they are capable. The programme ended with the showing of a film prepared by the physician superintendent and his staff.

The eighth reunion of the Association of Army Psychiatrists will be held at Slater's Restaurant 142 Strand London W.C.2 on Saturday Nov 18 at 7.30 P.M. Further particulars may be had from Dr J C Penson 1 Gatehill Road, Northwood Middlesex

Normally sickness benefit must be claimed within three days of the onset of the disability unless good cause can be shown for failure to do so. Under provisional regulations made by the Ministry of National Insurance a patient who is in hospital for not less than three months will be deemed during the first three months to have good cause for failing to notify his incapacity or to claim sickness benefit. For the short-stay patient the concession will end three weeks after his discharge from hospital. The concession does not extend to patients admitted or transferred to a home or other institution for convalescence. If there have been two or more periods in hospital each separated by not more than three weeks the period of deemed good cause will start at the earliest admission date.

Regional hospital boards have been reminded in a Minister of Health circular (H.B. 150) 1950 that any tendency towards too large a professional or staff element in the membership of hospital management committees should be avoided. In the Minister's view boards should not appoint a management committee's officers as members even of another committee unless there are exceptional strong reasons for doing so. In laying down general principles for the filling of vacancies on committees, the Minister last year declared that medical and dental members should normally be derived as implied by the Act from names proposed by the hospital staffs and not from other sources (H.B. 491) 1949; see *Lancet* 1949 II 951). Thus it is now explained was not intended to imply the complete exclusion of medical or dental members from other sources. Where a Board wish to include a general practitioner among the professional members they will no doubt consider any name put before them by the Executive Council, whom they are in any case obliged to consult or by the Local Medical or Dental Committee.

this method can also be used successfully in transvesical prostatectomy by introducing the solution through the bladder wall at the junction of the prostate and the neck of the bladder

Transvesical prostatectomy undoubtedly has its place, but in my experience 70-80% of prostates, including most of those weighing 20 g or more, are removed most easily and with the most complete control of haemorrhage by the retro pubic route. The transvesical route, with its relatively more difficult visualisation of the prostatic fossa, is reserved for the medium sized gland which is fibrous or infected. This route permits of complete diathermy dissection of firm adhesions—a type of case in which manual removal by the retropubic route usually involves such force that the incision in the capsule is excessively torn. The small fibrous and the irremovable malignant glands are, of course, treated perurethrally.

As regards antibiotics, in the urological fields there is every reason for using "blunderbuss" methods. All my cases are treated under an umbrella of sulphonamides, penicillin and streptomycin. Streptomycin is known to act very quickly, and unless infection is already present I cannot see the value of administering it, as Mr. Lee does, for three days before operation. I give the first dose with the preoperative medication and continue it for five days postoperatively (the catheter being removed on the second to fourth day), in this way the maximum effect is obtained at the crucial period.

Finally, I must disagree about the necessity for vasotomy. In the past two years, of nearly 150 cases on which I have operated only 1, with a grossly infected prostate and bladder, has had a vasotomy. Only 2 other cases showed any epididymitis—both due to proteus infection, and both before streptomycin became generally available.

Even a relatively soluble product like gelatin sponge, if wrapped round the balloon of a Foley catheter, is partly isolated from the antibiotics excreted in the urine and will thus harbour infection around the torn ends of the ejaculatory ducts and permit retrograde infection. This applies also to a Foley catheter alone if the balloon is fully inflated.

The methods described here so reduce postoperative haemorrhage that there is no necessity to introduce foreign bodies into the prostatic fossa, and epididymitis has become a thing of the past.—A. M. McMASTER, F.R.C.S.E. (Rochdale)

The Food We Eat—Sir Andrew Aguecheek complained that his wit had suffered through eating too much beef. Dr. Thrower (Oct. 21) blames lack of protein for our laziness. An experience of my own seems relevant. Four years ago, when the disparity of diets was greater than it is now, I spent some months working in a pathology department in Switzerland. With fat and protein in abundance, I soon found myself living, as my colleagues did, on two enormous meals a day. The time wasted here on breakfast elevenses, tea, and nightcap all were gained, at first sight, for work. But equally soon I found that at the very least two full hours were needed to eat and recover from a midday meal of Swiss dimensions, because of this, in spite of starting at 8 A.M., the hours of actual work put in at that Institute were exactly the same in sum as they are at home. Little and often keeps the belly light and the head clear.—BERNARD LENNON, M.D. (Postgraduate Medical School of London W 12)

Distinction Awards—I suggest that the Royal Medical Benevolent Fund would be an excellent recipient of the money from the distinction awards. On being informed that one of these had been given to me, my first intention was to return this money to the Ministry of Health. Thus, though satisfying to one's amour propre, is really, an empty gesture. The Ministry merely provides the machinery through which these awards are made on the suggestions and recommendations of our own profession. Some of us at an early stage considered that distinction awards would be a most remarkable and distasteful method of remuneration, and protested against it. We were then told that money had been laid aside for this purpose and could not be used in any other way—in fact that the whole system was already a fait accompli. A feeling of inertia is apt to come over one in face of such statements, but I suggest that we are not powerless or incapable of finding some other way of making use of this money for the benefit of the medical profession as a whole. There is surely no better way than to aid our less fortunate colleagues and their dependants, nor any better organisation through which to do this than the R.M.B.F.

The shamed secrecy with which these awards are surrounded compels me to adopt anonymity, so I sign myself, like the awards—A.B.C.

In England Now

ONE returns from Stratford refreshed by the sight of a countryside steeped in English history and bathed in autumnal beauty, and grateful for the opportunity to re-examine a fragment of Will Shakespeare's mind, for he was not only a poet and playwright but also a kindly philosopher, keenly aware of, and pondering with vast intelligence and sympathy all those problems of conduct in divers circumstances that afflict mankind. This year's feast included *Julius Caesar*, *Henry VIII*, *Much Ado*, and *Measure for Measure*. In all four the production, scenery, lighting, and décor were worthy of the author, only the acting left something to be desired—much of this, I thought, barely achieved mediocrity, though a better Pompey and Dogberry than those of Mr. George Rose. I do not hope to see. But how this fashion of underplaying has taken hold of our young actors! Some of them, in their zeal to throw away lines, come near to throwing away the whole play. The baby, were it not too magnificently robust, would follow the bath water. Mr. Quayle's Henry VIII, though it looked more Holbein than Holbein, disappointed by its childish petulance. Instead of a great and awe-inspiring figure, the king became merely an enfant terrible, more likely to damage the furniture than shape the course of history.

* * *

"Many women are convinced that the onset of the 'change' marks not only the end of the child-bearing period but the end of her natural desire," says a helpful little pamphlet I received this morning. The many children who have based their hopes of a beating free adolescence on the same theory will be sad to hear that "this is definitely not the case."

* * *

"Are one-eyed people seasick?" asked a peripatetic colleague the other week. My friend J., the most determined man I know, has sailed small yachts for 30 years, and to him the joy of the game is in leaving one port and reaching another, the time between has always been a nauseous yellow-green hell. In 1914 he defeated the medicos at his third attempt by learning the Snellen types by heart, he is that sort of man. By grim poetic justice a sniper's bullet went in at his left eye and emerged through his right ear. Yet four years later he was sailing again, and he has gone on ever since. So has his seasickness. On our last trip together he brought half a dozen bottles of apple champagne, convinced that this would cure him. The bottles remained unopened, for when one is feeling sick there is nothing worse than the smell of apples.

News

The next session of the General Medical Council will open on Tuesday Nov. 28 at 2.15 p.m. when Prof. David Campbell the president will deliver an address.

In England and Wales notifications of poliomyelitis in the week ended Oct. 21 were: paralytic 197 (223) non-paralytic 81 (85) total 278 (308). The figures for the previous week are in parentheses.

Prof. H. N. Green is to deliver the John Burns lecture to the Royal Faculty of Physicians and Surgeons, 242 St. Vincent Street, Glasgow, C.2 on Wednesday Nov. 15 at 5 p.m. He is to speak on the Fundamental Nature of Shock.

On Wednesday Nov. 22 at 6.30 p.m. Sir Lionel Whitty is to deliver the Hastings lecture at B.M.A. House, Tavistock Square, London W.C.1. His subject is to be Can Disease be Prevented? The lecture is open to the public and tickets may be obtained from the public relations department at B.M.A. House.

General practitioners staffing the Kingston and Malden Victoria Hospital have announced that they will ignore the management committee's instruction that no further patients shall be admitted after Oct. 31. The committee intends to convert this hospital into a gynaecological unit, thus increasing the maternity beds at the nearby General Hospital.

The British Postgraduate Medical Federation offers travelling fellowships to doctors training as specialists who hold an appointment or are engaged in postgraduate study at one of the London undergraduate or postgraduate teaching hospitals. Applications should be sent to the secretary of the federation, 3 Gordon Square, W.C.1 before Dec. 1.

At a conference in London on Oct. 24 Prof. A. L. Goodhart K.C. pointed out that last year 3955 car drivers had been found guilty of reckless or dangerous driving, yet only 358 had been disqualified. The feebleness of the magistrates was shown by the fact that the 1682 convictions for driving under the influence of drink or drugs led to only 54 prison sentences without the option of a fine. Mr. Kingsley Martin, editor of the *New Statesman*, did not see why withdrawal of licence should not be automatic in many cases and prison the only penalty for dangerous driving.

THE SURGERY OF THE SYMPATHETIC NERVOUS SYSTEM*

SIR JAMES LEARMONTH

K.C.V.O., C.B.E., Ch.M. Glasg., F.R.C.S.E.

REGIUS PROFESSOR OF CLINICAL SURGERY AND PROFESSOR OF SURGERY, UNIVERSITY OF EDINBURGH

IN 1937 I reviewed this subject for the *British Journal of Surgery*, at the end of fourteen years of what I then called the modern period of the surgery of the sympathetic system. Another fourteen years have passed, and it may be profitable to consider what changes they have brought in our knowledge and in our practice. I shall not trouble you with statistical data or with many operative details, but I shall try to indicate my present views, especially if they have changed during the last fourteen years. My lecture will therefore be in the most general terms, and its purpose will be one that has, I hope, always guided me—one that I stated on the other occasion when I spoke in this hall (Learmonth 1935).

'I dare say,' I said then, "that many of you are familiar with the remark of Claude Bernard's philosophic physiologist concerning the arrangement of the autonomic nervous system, that nature thought it prudent to remove these important phenomena from the caprice of an ignorant will. It is equally important that there should not be any capricious surgical interference with its functions."

Anatomy

In the last fourteen years there have been some notable contributions to our knowledge of the anatomy of the sympathetic nerves, for G. A. G. Mitchell, with patient accuracy, has completed his dissections of the nerves to the abdominal and pelvic viscera (Mitchell 1935a and b, 1938, 1940). Of particular interest at a time when even the most uninformed are ardent controversialists, is Mitchell's (1947) analysis of the origin and distribution of the nerves dealt with in operations for hypertension. His dissections show that after most of the usual procedures sympathetic filaments may still reach the abdominal contents along the aorta and along the esophagus, in the para-aortic nerves when present, and in the phrenic nerves, and that it is exceedingly difficult to denervate the kidneys completely. On anatomical grounds, he advised, as the optimum procedure, "bilateral resection of the sympathetic trunks from the fourth thoracic to the third lumbar ganglia and removal of the splanchnic nerves." I shall return to this matter when I come to speak briefly about the operative treatment of hypertension.

Another important piece of anatomical work done in the interval is the demonstration by Boyd and Monro (1949) that there may be ganglion cells belonging to the postganglionic neurone of the thoracolumbar outflow in the spinal nerves themselves. Both these cells and their preganglionic connections may escape in the standard operations of sympathectomy. Their presence and their numbers help to account for certain incomplete results which are seen after sympathectomy, and this possibility must be added to the other well known reasons for incomplete results—namely inadequate removal of the nerves concerned and regeneration of sympathetic fibres. Although the great capacity for regeneration possessed by sympathetic fibres has been repeatedly shown in the experimental animal I am satisfied that of the incomplete results in my own material more should be ascribed to original incomplete removal of nerves than to subsequent regeneration of fibres.

* From the Simpson-Smith memorial lecture delivered in the hall of the Medical Society of London on June 7, 1950.

There is one important change of opinion, which has both anatomical and physiological implications. Previously it was thought that after removal of ganglia or division of postganglionic neurones, the muscles of the blood vessels in the denervated territory became oversensitive to circulating adrenaline, and so every endeavour was made to make interruptions of vasomotor nerves preganglionic in level. It is now known that although this sensitisation occurs in animals, it does not occur in man, and particularly in the denervation of the upper extremity there is now no physiological obligation to make a sympathectomy operation preganglionic, although I believe that one should spare the stellate ganglion when possible and so avoid the occurrence of Horner's syndrome.

Finally, largely as the result of the clinical work of J. C. White (1947) our information about the anatomical paths taken by visceral afferent nerves accompanying the thoraco-abdominal outflow has been much extended, and has been given a precision approaching that of our knowledge of somatic innervation. I shall deal with these routes later.

Physiology

The search goes on for sympathetolytic drugs, but up to the present none tested in my clinic is wholly suitable. To be useful clinically, such a drug must act when given by mouth, must maintain its action over a sufficiently long period, and must not give rise to undesirable side effects, such as a considerable fall in blood-pressure. I feel that limiting the effect of these drugs to a given territory by injecting them intra-arterially is not a justifiable therapeutic procedure, in general, reflex methods of producing vasodilatation will be equally efficacious and less trying to the patient, and it cannot be too strongly emphasised that surgery is the only precise therapeutic method of limiting sympathetolysis that we possess at the present time. Of recent years we have been provided with a great deal of useful information about the physiological effects of sympathectomy on the circulation by Prof. Henry Barcroft and his colleagues (Barcroft and Millen 1939, Barcroft et al 1943, Barcroft and Edholm 1945, 1946a and b).

Surgery

Over the years, there has been a reduction in the number of conditions for which operations on the sympathetic system are advised. At the present time, sympathectomy has an established place in the treatment of certain forms of ischaemia, of severe hyperhidrosis, of certain types of visceral pain and—perhaps less securely—of hypertension. It is seldom employed with the object of modifying visceral function. I need not remind you that we owe many refinements, both of application and of technique, to Telford (Telford and Simmons 1936, 1940) and to Paterson Ross (1946).

I shall first consider the risks attending operations on the sympathetic nervous system.

I have had one death after cervicothoracic sympathectomy, seventeen years ago. I believe from bleeding because of inefficient control of the superior intercostal artery, although necropsy was refused. I have had three deaths after lumbar sympathectomy: one from gas gangrene of the wound of undetermined origin, fourteen years ago, one on the operating table seven years ago, during a lumbar sympathectomy preliminary to dealing with a large traumatic arteriovenous popliteal fistula, a death for which necropsy did not provide an explanation, and one from acute aortic thrombosis possibly caused by ungentle retraction of the sclerotic aorta six years ago.

My operation mortality for the various more extensive operations I have used in the treatment of hypertension is just under 3% of all cases accepted for surgical treat-

THE SURGERY OF THE SYMPATHETIC NERVOUS SYSTEM*

SIR JAMES LEARMONTH

K.C.V.O., C.B.E., Ch.M. Glasg., F.R.C.S.E.

REGIUS PROFESSOR OF CLINICAL SURGERY AND PROFESSOR OF SURGERY, UNIVERSITY OF EDINBURGH

IN 1937 I reviewed this subject for the *British Journal of Surgery*, at the end of fourteen years of what I then called the modern period of the surgery of the sympathetic system. Another fourteen years have passed, and it may be profitable to consider what changes they have brought in our knowledge and in our practice. I shall not trouble you with statistical data or with many operative details, but I shall try to indicate my present views, especially if they have changed during the last fourteen years. My lecture will therefore be in the most general terms, and its purpose will be one that has, I hope, always guided me—one that I stated on the other occasion when I spoke in this hall (Learmonth 1938).

"I dare say," I said then, "that many of you are familiar with the remark of Claude Bernard's philosophic physiologist concerning the arrangement of the autonomic nervous system, that nature thought it prudent to remove these important phenomena from the caprice of an ignorant will. It is equally important that there should not be any capricious surgical interference with its functions."

Anatomy

In the last fourteen years there have been some notable contributions to our knowledge of the anatomy of the sympathetic nerves. For G. A. G. Mitchell, with patient accuracy, has completed his dissections of the nerves to the abdominal and pelvic viscera (Mitchell 1935a and b, 1938, 1940). Of particular interest, at a time when even the most uninformed are ardent controversialists, is Mitchell's (1947) analysis of the origin and distribution of the nerves dealt with in operations for hypertension. His dissections show that after most of the usual procedures sympathetic filaments may still reach the abdominal contents along the aorta and along the oesophagus, in the para aortic nerves when present, and in the phrenic nerves, and that it is exceedingly difficult to denervate the kidneys completely. On anatomical grounds, he advised, as the optimum procedure, "bilateral resection of the sympathetic trunks from the fourth thoracic to the third lumbar ganglia and removal of the splanchnic nerves." I shall return to this matter when I come to speak briefly about the operative treatment of hypertension.

Another important piece of anatomical work done in the interval is the demonstration by Boyd and Monro (1949) that there may be ganglion cells belonging to the postganglionic neurone of the thoracolumbar outflow in the spinal nerves themselves. Both these cells and their preganglionic connections may escape in the standard operations of sympathectomy. Their presence and their numbers help to account for certain incomplete results which are seen after sympathectomy and this possibility must be added to the other well known reasons for incomplete results—namely, inadequate removal of the nerves concerned and regeneration of sympathetic fibres. Although the great capacity for regeneration possessed by sympathetic fibres has been repeatedly shown in the experimental animal I am satisfied that of the incomplete results in my own material more should be ascribed to original incomplete removal of nerves than to subsequent regeneration of fibres.

* From the Simpson-Smith memorial lecture delivered in the hall of the Medical Society of London on June 7, 1950.

There is one important change of opinion, which has both anatomical and physiological implications. Previously it was thought that after removal of ganglia or division of postganglionic neurones, the muscles of the blood vessels in the denervated territory became oversensitive to circulating adrenaline, and so every endeavour was made to make interruptions of vasomotor nerves preganglionic in level. It is now known that although this sensitisation occurs in animals it does not occur in man, and particularly in the denervation of the upper extremity there is now no physiological obligation to make a sympathectomy operation preganglionic, although I believe that one should spare the stellate ganglion when possible and so avoid the occurrence of Horner's syndrome.

Finally, largely as the result of the clinical work of J. C. White (1947) our information about the anatomical paths taken by visceral afferent nerves accompanying the thoraco abdominal outflow has been much extended, and has been given a precision approaching that of our knowledge of somatic innervation. I shall deal with these routes later.

Physiology

The search goes on for sympathetolytic drugs, but up to the present none tested in my clinic is wholly suitable. To be useful clinically, such a drug must act when given by mouth, must maintain its action over a sufficiently long period, and must not give rise to undesirable side effects, such as a considerable fall in blood-pressure. I feel that limiting the effect of these drugs to a given territory by injecting them intra arterially is not a justifiable therapeutic procedure, in general reflex methods of producing vasodilatation will be equally efficacious and less trying to the patient, and it cannot be too strongly emphasised that surgery is the only precise therapeutic method of limiting sympathectomy that we possess at the present time. Of recent years we have been provided with a great deal of useful information about the physiological effects of sympathectomy on the circulation by Prof. Henry Barcroft and his colleagues (Barcroft and Millen 1939, Barcroft et al. 1943, Barcroft and Edholm 1945, 1946a and b).

Surgery

Over the years there has been a reduction in the number of conditions for which operations on the sympathetic system are advised. At the present time sympathectomy has an established place in the treatment of certain forms of ischaemia, of severe hyperhidrosis, of certain types of visceral pain, and—perhaps less securely—of hypertension. It is seldom employed with the object of modifying visceral function. I need not remind you that we owe many refinements both of application and of technique, to Telford (Telford and Summons 1936, 1940) and to Paterson Ross (1946).

I shall first consider the risks attending operations on the sympathetic nervous system.

I have had one death after cervicothoracic sympathectomy, seventeen years ago, I believe from bleeding because of inefficient control of the superior intercostal artery, although necropsy was refused. I have had three deaths after lumbar sympathectomy—one from gas gangrene of the wound of undetermined origin, fourteen years ago—one on the operating table seven years ago, during a lumbar sympathectomy preliminary to dealing with a large traumatic arteriovenous popliteal fistula, a death for which necropsy did not provide an explanation, and one from acute aortic thrombosis possibly caused by ungentle retraction of the sclerotic aorta six years ago.

My operation mortality for the various more extensive operations I have used in the treatment of hypertension is just under 3% of all cases accepted for surgical treat-

ment, including what might be regarded as unavoidable deaths—those for example before any operation was done, and those occurring out of hospital or nursing home, in the intervals between operations. If one accepts occasional ill fortune, operations on the sympathetic nervous system are safe. I turn to their applications.

DIVISION OF AFFERENT PATHWAYS

Visceral Pain

Sympathetic denervation for pain originating in viscera has been—and still is—utilised more often on the Continent and in America than in this country, possibly because of the original insistence of British physiologists that the sympathetic system itself was a purely efferent one. However a considerable proportion (about half) of the fibres in the splanchnic nerves convey afferent impulses from viscera, some of which are of pain, and there may be, as in the case of the heart and aortic arch, more direct fibres to the ganglionated chains. It is clear that effective sensory denervation of a viscus can be secured either (1) if the viscus has a vascular pedicle, by interrupting the nerves accompanying the vessels, or (2) by interrupting a sufficient length of the ganglionated chain, or (3) by division of the appropriate spinal posterior roots.

The principle has been most often applied to the treatment of angina pectoris and of dysmenorrhœa, and my own experience has been confined to the former. Two procedures are available: paravertebral injection of alcohol round the upper four thoracic sympathetic ganglia on the left side, or operative removal of the same ganglia (White and Bland 1948). I now prefer the latter. Injections of alcohol are not infrequently followed by troublesome intercostal neuritis. The operation can be done quickly and without undue risk, although one must be careful to soak the paravertebral ganglia with procaine solution before beginning to manipulate them. White himself, outstanding expert though he is in the technique of paravertebral injection, has come to prefer the open operation, as have also Lindgren and Olivecrona (1947). I used to think that if there were attacks of pain while the patient was at rest, sympathetic interruption was contra-indicated—but I am not so sure of this now.

Renal Pain

My experience of denervation of the renal pedicle for pain of renal origin is now long past, but my few cases—and I live in daily association with one—lead me to endorse Oldham's (1936) favourable view of the procedure, in properly selected cases.

Causalgic Pain

Although in the last war causalgia was less frequent than in the war of 1914–18, a sufficient number of cases accumulated in which the characteristic spontaneous burning pain, started or aggravated by emotional stimuli, left the diagnosis in no doubt. While mild examples of causalgia may be expected to clear up without treatment, it is now definitely established that sympathetic denervation of the affected limb, usually preceded by diagnostic paravertebral procaine block, is efficacious in dealing with the pain. In a small proportion of cases, repeated procaine block may be sufficient of itself. In a series of 22 cases carefully reviewed by my colleague, A. J. Slessor (1948), in 17 sympathetic denervation permanently abolished the pain and in 2 repeated procaine paravertebral block. In the remaining 3 cases spontaneous improvement in the pain has occurred. My own more limited experience has been similar.

Carotid Sinus Syndrome

The only purpose for which periarterial sympathectomy remains the operation of choice is as the procedure for denervating an oversensitive carotid sinus on one or

both sides. This denervation deals with any of the three types of attack to which these patients may be prone, characterised either by cardiac arrest, or by widespread vasodilatation or by epileptiform attacks. A sufficient number of cases of bilateral denervation have been carefully enough studied—including one by Turner and myself (1948)—to show that the procedure is not followed by any untoward after-effects. Recently it has been found that relief from the attacks may also be obtained by intracranial division of the glossopharyngeal nerve on one or both sides (Ray and Stewart 1948), which seems to me on the whole a more formidable procedure than bilateral carotid denervation.

Sympathectomy to Modify Visceral Function

I am enough of a diehard to believe that division of their sympathetic nerves has an occasional place in the treatment of congenital dilatation of the ureters, bladder, and large intestine. It has to be done early, before the age of three or so, or, more accurately, at least in the case of the urinary tract, before organic changes have occurred in its walls. I defend my stubbornness by my experience in a number of cases in which congenital dilatation of the urinary tract and of the large intestine coexisted: for I have had some cases in which only one of these was cured by an extensive sympathectomy. Why I do not know, nor can I predict which defect will benefit, except that in one of my cases, in which the vesical condition was cured whereas the intestinal remained unaltered, there was a small area of sensory loss in the fifth sacral segment.

DIVISION OF EFFERENT FIBRES

Hyperhidrosis

So safe an operation is sympathetic denervation of a limb, that when a patient suffers from hyperhidrosis of the hands or feet interfering with the pursuit of a profession or presenting any social or economic difficulty, operation may be confidently recommended. There is a psychological aspect to these cases, which must not be underestimated, and I have been glad to relieve from anxiety patients following so different occupations as medicine, chiropody, and optometry.

Ischæmia

Ischæmia may be due to vasospasm, or it may follow any form of interruption of a main or branch artery. My accumulated experience has taught me to take a long term view of these cases, and not to be stampeded into operations of so-called emergency. The physiological effect of sympathetic denervation on the arterial tree of a normal extremity was first studied in detail by Theiss (1933) on dogs, and his findings apply to all normally constructed arteries except possibly the largest. After ligation of the femoral artery, immediate sympathetic denervation produced an increase of more than 100% in blood flow through collaterals, for the first week. Thereafter there occurred a rapid fall until about the eighth week, after which the increase in blood flow remained stable (for at least ten months) at between 40 and 50% higher than its original level. We have found that these changes cannot be correlated with return of blood pressure, which is almost complete in forty-eight hours. Since the volume flow through a vessel varies with the fourth power of its radius, a very small amount of permanent vasodilatation is sufficient to provide for this exceedingly substantial permanent increase in blood flow. It may not provide all the blood required by energetically working distal muscles, but it is more than ample for the nutrition of the resting limb, because in favourable circumstances the unimproved collateral circulation is quite sufficient for this.

Of late years it has seemed to me that too early sympathectomies in cases of relatively acute blockage of

arteries may by their very success in increasing blood-flow remove the "natural" stimulus toward the formation of additional collateral vessels. In young patients that may not matter a great deal at the time of the block but the greater the total calibre of the collateral vessels that patients make, the more secure the limb will be in the later decades of life, when obliterative vascular disease is common. Therefore I think it wise to tide over most ischemic emergencies by conservative treatment, which means warmth, rest, and anticoagulant drugs, until natural improvement seems to be at an end. In the arm this is usually relatively soon, in the leg it takes up to three or four months, after which I have an idea that, although undoubtedly the formation of collateral vessels continues, it is mostly confined to the short channels which form in any intra-arterial organised thrombus, whose only connections, and they are unimportant ones, are with the vasa vasorum. Moreover I share White's (1949) experience that when the nutritional state of a distal part is extremely doubtful, immediate sympathetic denervation may precipitate gangrene by increasing oedema about the proximal limits of the doubtful area. Therefore when the main artery of a leg or a major branch is interrupted in young people, I believe it to be good judgment to carry out sympathetic denervation of the leg after a suitable interval, as a kind of "old age insurance", the same policy is also usually the best when the patient is older.

The end result of denervating an unblocked arterial tree, for example in uncomplicated Raynaud's disease, is approximately the same quantitatively, although not predictable with accuracy. In such conditions, after sympathetic denervation the smaller arteries and arterioles of an extremity are left slightly larger, but continually larger, than before operation, provided that the patient does not foolishly expose either hands or feet or both to extreme cold or to prolonged cold.

The data in the problem change when general or local arterial disease is present—i.e., in arteriosclerosis, in thromboangitis obliterans, and in Raynaud's disease as soon as attacks are accompanied by severe blanching. In such cases I am accustomed now to pose myself two problems: is it possible to get blood *up* to the threatened part, and is it possible to get blood *into* the threatened part? If one can get blood to flow at all through a part which does not vary very much in its demands for blood, it has always surprised me that its minimum requirements should be so small, but the blood must keep flowing. In patients with the not very uncommon condition of aortic thrombosis, blood flow through the feet may be reduced to as little as 0.6 ml./100 c.c./min. as compared with the average normal figure of 2.3 ml./100 c.c./min., without the appearance of any grave nutritional lesions. Eleven months after bilateral lumbar sympathectomy for aortic thrombosis we have recorded as high a flow as 3.8 ml./100 c.c./min., which is 65% more than the normal figure. Little is known of the basal nutritional requirements of the digits, although from the composition of their tissues it is likely to be small, and the large blood-flow which normally goes on through digits is designed for general temperature regulation rather than for local nutrition. Another example of a condition in which quite an adequate flow is maintained to distal parts is widespread calcification of peripheral vessels not complicated by thrombosis, a by no means uncommon finding in clinical practice and sometimes an unexpected one. Widespread medial sclerosis may not be associated with diminution of calibre or with loss of continuity of the intima.

When one is considering the desirability of sympathetic denervation in cases where the vessels are diseased, I believe that one can practically always decide whether

it is possible to get blood to a threatened part by determining whether collateral pulses are present or absent. In the arm this does not often need a greater familiarity with the arterial tree than is required of a second-year student, although occasionally exceptions occur. In the leg the pulses round the knee are important: above all the pulse of the anastomotica magna artery, on the anterior aspect of the internal condyle of the femur, is a reassuring sign that a conduit of some size is patent, it should be remembered also that the dorsalis pedis pulse is absent in 12% of normal subjects, its place being taken by the peroneal artery; the pulse of which may be felt either in front of the external malleolus or on the lateral surface of the tuberosity of the os calcis. The vessels which provide these important pulses can all be dilated by lumbar sympathectomy, as can be shown by observing the return of the pulses about the ankle, or by a marked increase in their force, immediately after operation. This procedure may be confidently employed to increase their calibre by an amount which will materially increase the blood flow through them, to an extent that will safeguard the nutrition of the digits of hands or feet.

To get sufficient blood *into* a threatened part is often more difficult. The extremes of difficulty are provided by the usual finding in diabetic arteriosclerotics, that all the digital vessels of one or more toes are extensively diseased, and by the dorsal ulcer over the tarsal bones, often seen in cases of thromboangitis obliterans which may be the result of obliteration of all the vessels to that area of skin. These irreversible conditions cannot be remedied by sympathectomy—amputation is inevitable. In general this may be more distal in diabetics than in those suffering from Buerger's disease or from arterio-sclerosis. I have not been impressed by the results of sympathectomy in reducing the extent of amputations—perhaps because from a psychological point of view, I believe that the first amputation should be the final one. Even though at first a lower amputation may seem satisfactory the long term outlook is not good.

In my own experience I have found that an increase in claudication distance seldom follows sympathectomy, and that when it does, the distance gained is hardly ever considerable, because the blood debt is usually too great. Claudication can be helped in simpler ways.

Certain things I have learned. First, that it is unwise to give an unguardedly good prognosis in any but the earliest cases of Raynaud's disease, for I believe that organic changes in the digital vessels are earlier and more extensive than are generally supposed, and that operation is best avoided in the cases secondary to the use of vibrating tools, or those which appear after digital sepsis. Secondly, perhaps my greatest regret now—though I am conservatively minded—is that I used to refuse the possibility of help from sympathectomy to too many patients in the older age groups. This is the group in which most complications are to be expected, the most anxious being the occurrence of postoperative pain. This is not particularly common, but its incidence is unpredictable. It begins some ten to fourteen days after sympathectomy, is worst at night, and lasts from a day or so up to three months or more. It takes the form of a dull ache of great intensity, usually deep in the lower third of the thigh, to which may be added hyperaesthesia of the skin of the thigh. It does not conform to any anatomical territory, and its origin is obscure though it is probably a manifestation of ischemic neuritis. None of my five cases occurred in a female, and in none was any unusual operative difficulty encountered. Two could be classed as severe. The choice between the hope of retaining a patient in this group as a biped, and the dread of postoperative pain for which no treatment except analgesic drugs is available, is a difficult one and must be determined on the merits of

each case. And thirdly, the need for dealing with even the smallest of septic lesions before operating.

I do not employ paravertebral injections except as therapeutic tests, and as an additional and in my view valuable procedure in the treatment of acute axillary or iliofemoral venous thrombosis.

Hypertension

The form of hypertension that has been most often treated by sympathectomy is essential hypertension, possibly persisting after pregnancy. Most of the cases in all recorded series belong to that category, and in the absence of any real knowledge of the pathogenesis of essential hypertension, all forms of treatment, including operative treatment, must be entirely empirical. It is as wrong to deny to sympathectomy a place in the symptomatic treatment of this condition as it is to claim for sympathectomy a uniformly favourable influence upon its symptoms and progress. I know of no rules by which those cases in which a reduction in blood pressure can be hoped for may be confidently selected, so my tendency is coming to be to reserve operation for the relief of symptoms and signs, even in cases of so called malignant hypertension. If life is also prolonged, it is by the postponement of cerebral vascular incidents. I feel strongly that the risks of any such operative treatment should be reduced as much as possible. In general this can be done by restricting its scope, and at this point I must return to consider for a moment the views of Professor Mitchell (1947) on the anatomical adequacy of the various operations which have been proposed. It will be remembered that Mitchell considered that sympathetic fibres could reach the abdominal viscera around the oesophagus, around the aorta, and in the phrenic nerve, and he advised that the origins of the first two of these additional contributions could be dealt with by extending the operation from the third thoracic to the third lumbar ganglion inclusive, which means a combined thoraco-abdominal approach. I have never thought it necessary to remove the thoracic chain as high as this. I am coming to the view that for the relief of symptoms, which is all that is reasonably certain after the operation, a sub-diaphragmatic operation may be sufficient in a large enough proportion of cases to make it the rule. In such an operation the fibres which tend to escape division are those destined for the renal plexus from the trunks of the splanchnic nerves and from the aortic and mesenteric plexuses, and dissection of this area shows how complicated the arrangement of these branches may be. The best plan to include them is to make a clean dissection of the nerves on each pillar of the diaphragm and of the lumbar sympathetic trunk and its branches, down to the third lumbar vertebra. This procedure incidentally avoids the risk of postoperative intercostal neuritis, although in my own thoraco-abdominal series of cases this has been a rare complication.

One must be prepared to accept disappointments from the operation, and certain possible unpleasant post-operative effects. The first of these is postural hypotension, which can be very troublesome for the first few months, even up to a year. Its occurrence in a marked form is not any guarantee that the blood pressure will not subsequently and even quite rapidly rise to its pre-operative level. Tachycardia, as a rule postural but sometimes even at rest, may lead to some breathlessness, and pain in the distribution of an intercostal or subcostal nerve exposed at operation, or in the distribution of the genitofemoral nerve in cases where dissection has been difficult, may occasionally be disabling. After the more extensive sympathectomies, in my experience in about one fifth of the cases severe attacks of the Raynaud phenomenon in the hands may be most uncomfortable and in extreme cases disabling. Bilateral removal of the first and second lumbar ganglia leads to sterility but not

to impotence in the male, this is so constant a finding that it can be used to determine the completeness or otherwise of the ganglionectomy. About half the patients consider that they are more placid after operation, an improvement which has a beneficial effect on their domestic life and on their social activities. Like other investigators, I have found that headache is the symptom which is most improved, the headache disappearing or being improved in over 90% of my cases. And no-one can deny that some of the pathological signs—for example papilloedema—disappear at least temporarily after operation.

It will thus be seen that one can expect certain hypertensives to be grateful for operation and one can also expect in a proportion of cases that their friends will also be grateful. If it is possible to achieve these results by the more limited subdiaphragmatic procedure, the period of hospitalisation and the period of convalescence will be much reduced and the possible physiological and economic results of operation will be so much the better. I propose to continue to operate upon a proportion of hypertensive patients. I select them myself. I refuse those who are symptomless, those who have severe cardiac disease, and those who have cerebral palsies. The oldest in my series was 54, which is probably too old, and in a doubtful case I would give the chance of operation to a man rather than to a woman, though some men are very depressed after the second side is done. Women do better on any treatment. I am not always right, but then who is? What matters is that I naturally select patients for operation with all the earnestness and sense of responsibility of which I am capable.

Conclusion

The surgery of the sympathetic nervous system should be one continuous observation of human physiology, and it is greatly to the credit of our art that in Britain this has been so largely true. Indeed I would go so far as to say that it is quite wrong for surgeons to undertake these procedures, unless they have a good basic understanding of the physiological and physical principles that are involved. The mere multiplication of operations is useless. Fifty surgeons who are not physiologically minded will not advance surgical science further than one surgeon who is not physiologically minded. At the present time I would define the object of intelligently used surgery of the sympathetic system as *preservation*. Sometimes of tissue, even of a limb, sometimes of bodily comfort, sometimes of mental happiness, sometimes, though less often, of life itself.

THE RICE DIET IN THE TREATMENT OF HYPERTENSION

A REPORT TO THE MEDICAL RESEARCH COUNCIL*

IN 1944 Kempner (1944a and b) reported the result of treating a series of patients suffering from renal and hypertensive vascular disease with a rice diet. In further papers (1945, 1946, 1948, 1949), he has reviewed the effects of this treatment and has produced impressive evidence of improvement, not only in the level of the blood pressure and in the well being of his patients, but also in such objective findings as heart size, eye ground changes, and electrocardiographic tracings. Kempner's results have been confirmed by some (Behrendt and Burgess 1947, Flipse and Flipse 1947, Rosenberg et al 1948, Contratto and Rogers 1948, Lichtwitz et al 1950) and refuted by others (Ayman 1949, Chasis et al 1949, 1950, Schroeder 1948, Schroeder et al 1949).

At the request of the Medical Research Council, a small committee was formed to carry out in this country a clinical trial of the rice diet. This paper presents the results so far obtained in a short term trial. There are, as yet, no results of its use over a long period, which might compare with recent reports (Kempner 1949, Kempner et al 1949).

* By a committee with the following members: Dr D R CAMERON, physician to the York County Hospital, Dr D M DUNLOP, professor of therapeutics in the University of Edinburgh, Dr ROBERT PLATT, professor of medicine in the University of Manchester, Dr M L ROSENHEIM, professor of medicine, University College Hospital, London, and Dr E P SHARPEY-SCHAFER, professor of medicine, St Thomas's Hospital, London. Series of cases were observed at all these centres.

COMPOSITION OF DIET

The diet used was that described by Kempner (1948), and his directions were closely followed. It consisted only of rice, fruit, fruit juice, and sugar or syrup, with added vitamins. A supplement of ferrous sulphate was also given to certain patients. Patients were encouraged to eat 250-350 g of rice (dry weight) daily, but the exact amount that could be tolerated varied. The rice was boiled or steamed in water, with no added salt, milk, or fat. Some preferred it served dry, others wet. It was flavoured with sugar, lemon juice, or fruit. The fluid intake was usually limited to 1 litre in the twenty four hours. Such a diet should provide at least 2000 calories per day, containing about 20 g of protein, 5 g of fat, and not more than 150 mg of sodium in the twenty four hours. Care was taken to see that no drugs were given unless specially ordered, and that such drugs contained little or no sodium. Chemical analysis of a day's diet, the duplicate of that eaten by one of the patients, showed

Sodium	5.27 m.eq (121 mg)
Potassium	49.00 m.eq (191 g)
Chloride	5.5 m.eq (195 mg)
Nitrogen	3.14 g (equivalent to 19.6 g of protein)

A sample menu is given in table 1. In this, the figures for sodium and chloride have been taken from tables

SELECTION OF CASES

It was decided to select for treatment severe and moderately severe cases of hypertension, whether due to essential hypertension or to chronic renal disease. As far as possible, patients were selected who, during at least ten days in hospital on moderate bed rest, showed an average diastolic blood pressure of at least 120 mm Hg. The blood pressure was recorded daily by the same observer after the patient had rested quietly in bed for

TABLE 1—RICE DIET FOR HYPERTENSION (U.C.H.), YIELDING 2000 CALORIES

	Carbohydrate (g)	Protein (g)	Fat (g)	Sodium (mg)	Chloride (mg)
Breakfast					
Grapefruit (prepared) 5 oz	7.5	1.0	tr	2.0	2.0
Boiled rice (dry weight) 2 oz	49.2	3.6	0.6	3.6	15.4
Sugar 1 oz	29.7	tr	tr	0.1	tr
Orange juice 8 oz	21.6	1.6	tr	4.0	2.4
	108.0	6.2	0.6	9.7	19.8
Mid-morning					
Lemon juice 1½ oz, with water 5 oz	0.6	0.1	tr	0.5	0.8
Sugar ½ oz	14.8	tr	tr	0.05	tr
	15.4	0.1	tr	0.55	0.8
Dinner					
Boiled rice (dry weight) 3 oz	73.8	5.4	0.9	5.4	23.1
Golden syrup ½ oz	12.2	0.05	—	38.3	5.9
Blackcurrants, raw 5 oz	9.5	1.3	tr	4.0	21.0
Added sugar 1 oz	29.7	tr	—	0.1	tr
Black grapes 6 oz	26.4	1.2	tr	3.0	tr
	151.6	7.95	0.9	50.8	50.0
Tea					
Boiled rice (dry weight) 1 oz	24.6	1.8	0.3	1.8	7.7
Sugar 1 oz (for rice and fruit drink)	29.7	tr	—	0.1	tr
Banana slices 1½ oz (added to rice)	8.2	0.45	tr	0.45	33.4
Fruit drink made of					
Orange juice 2 oz	5.4	0.4	tr	1.0	0.6
Lemon juice 2½ oz	1.25	0.25	tr	1.0	1.75
	69.15	2.9	0.3	4.35	43.45
Supper					
Boiled rice (dry weight) 3 oz	73.8	5.4	0.9	5.4	23.1
Sugar ½ oz	22.2	tr	—	0.1	tr
Fresh peaches 5 oz	13.0	1.0	tr	4.0	tr
Orange juice 8 oz	21.6	1.6	tr	4.0	2.4
	130.6	8.0	0.9	13.5	25.5
Before retiring					
Dessert cherries 5 oz	17.0	1.0	tr	4.0	tr
	491.75	26.15	2.7	82.9	139.55

The figures in this table are taken from those given by McCance and Widdowson (1946)

each case. And thirdly, the need for dealing with even the smallest of septic lesions before operating.

I do not employ paravertebral injections except as therapeutic tests, and as an additional and in my view valuable procedure in the treatment of acute axillary or iliofemoral venous thrombosis.

Hypertension

The form of hypertension that has been most often treated by sympathectomy is essential hypertension, possibly persisting after pregnancy. Most of the cases in all recorded series belong to that category, and in the absence of any real knowledge of the pathogenesis of essential hypertension, all forms of treatment, including operative treatment, must be entirely empirical. It is as wrong to deny to sympathectomy a place in the symptomatic treatment of this condition as it is to claim for sympathectomy a uniformly favourable influence upon its symptoms and progress. I know of no rules by which those cases in which a reduction in blood pressure can be hoped for may be confidently selected, so my tendency is coming to be to reserve operation for the relief of symptoms and signs, even in cases of so called malignant hypertension. If life is also prolonged, it is by the postponement of cerebral vascular incidents. I feel strongly that the risks of any such operative treatment should be reduced as much as possible. In general this can be done by restricting its scope, and at this point I must return to consider for a moment the views of Professor Mitchell (1947) on the anatomical adequacy of the various operations which have been proposed. It will be remembered that Mitchell considered that sympathetic fibres could reach the abdominal viscera around the oesophagus, around the aorta, and in the phrenic nerve, and he advised that the origins of the first two of these additional contributions could be dealt with by extending the operation from the third thoracic to the third lumbar ganglion inclusive, which means a combined thoraco-abdominal approach. I have never thought it necessary to remove the thoracic chain as high as this. I am coming to the view that for the relief of symptoms, which is all that is reasonably certain after the operation, a sub-diaphragmatic operation may be sufficient in a large enough proportion of cases to make it the rule. In such an operation the fibres which tend to escape division are those destined for the renal plexus from the trunks of the splanchnic nerves and from the aortic and mesenteric plexuses, and dissection of this area shows how complicated the arrangement of these branches may be. The best plan to include them is to make a clean dissection of the nerves on each pillar of the diaphragm and of the lumbar sympathetic trunk and its branches, down to the third lumbar vertebra. This procedure incidentally avoids the risk of postoperative intercostal neuritis, although in my own thoraco-abdominal series of cases this has been a rare complication.

One must be prepared to accept disappointments from the operation, and certain possible unpleasant post-operative effects. The first of these is postural hypotension, which can be very troublesome for the first few months, even up to a year. Its occurrence in a marked form is not any guarantee that the blood pressure will not subsequently and even quite rapidly rise to its pre-operative level. Tachycardia, as a rule postural but sometimes even at rest, may lead to some breathlessness, and pain in the distribution of an intercostal or subcostal nerve exposed at operation, or in the distribution of the genitofemoral nerve in cases where dissection has been difficult, may occasionally be disabling. After the more extensive sympathectomies, in my experience in about one fifth of the cases severe attacks of the Raynaud phenomenon in the hands may be most uncomfortable and in extreme cases disabling. Bilateral removal of the first and second lumbar ganglia leads to sterility but not

to impotence in the male, this is so constant a finding that it can be used to determine the completeness or otherwise of the ganglionectomy. About half the patients consider that they are more placid after operation, an improvement which has a beneficial effect on their domestic life and on their social activities. Like other investigators, I have found that headache is the symptom which is most improved, the headache disappearing or being improved in over 90% of my cases. And no one can deny that some of the pathological signs—for example papilloedema—disappear at least temporarily after operation.

It will thus be seen that one can expect certain hypertensives to be grateful for operation and one can also expect in a proportion of cases that their friends will also be grateful. If it is possible to achieve these results by the more limited subdiaphragmatic procedure, the period of hospitalisation and the period of convalescence will be much reduced and the possible physiological and economic results of operation will be so much the better. I propose to continue to operate upon a proportion of hypertensive patients. I select them myself. I refuse those who are symptomless, those who have severe cardiac disease, and those who have cerebral palsies. The oldest in my series was 54, which is probably too old, and in a doubtful case I would give the chance of operation to a man rather than to a woman, though some men are very depressed after the second side is done. Women do better on any treatment. I am not always right, but then who is? What matters is that I naturally select patients for operation with all the earnestness and sense of responsibility of which I am capable.

Conclusion

The surgery of the sympathetic nervous system should be one continuous observation of hominal physiology, and it is greatly to the credit of our art that in Britain this has been so largely true. Indeed I would go so far as to say that it is quite wrong for surgeons to undertake these procedures, unless they have a good basic understanding of the physiological and physical principles that are involved. The mere multiplication of operations is useless: fifty surgeons who are not physiologically minded will not advance surgical science further than one surgeon who is not physiologically minded. At the present time I would define the object of intelligently used surgery of the sympathetic system as preservation. Sometimes of tissue, even of a limb, sometimes of bodily comfort, sometimes of mental happiness, sometimes, though less often, of life itself.

TABLE V—RENAL FUNCTION TESTS BEFORE AND DURING RICE DIET

Test	No of cases	Averages	
		Before diet	During diet
Urea-clearance	28	70 %	42.5 %
Urea-concentration test	4	3.5 g per 100 ml	2.1 g per 100 ml
Endogenous-creatinine clearance	5	57 ml per min	46 ml per min
Inulin-clearance	3	64 ml per min	43 ml per min
Diodone-clearance	3	280 ml per min	251 ml per min

cases known to have renal insufficiency, there is substantial evidence that renal function becomes impaired while patients are on the rice diet.

As is to be expected on so low a protein intake, the blood urea fell in almost every case (table IV). This fall might account for some diminution in the power to produce a urine of high specific gravity, but could not explain the other changes in renal function tests (table V). Thus, in some cases a fall in the inulin and diodone clearances, in others a lowered endogenous creatinine clearance, and in yet others a fall in phenolsulphone phthalein excretion was observed. This impaired renal function seems to be reversible, as there was a prompt improvement when the rice diet was stopped.

The plasma protein level was well maintained on the diet. There was no consistent change in the plasma cholesterol, but, in general, patients with high original levels tended to show a considerable fall, while those with normal or low original figures showed little change. There was no correlation between fall in the plasma-cholesterol and fall of blood pressure.

ILLUSTRATIVE CASE RECORDS

Case 1—A married woman, aged 42, was admitted to hospital with severe benign essential hypertension, her chief complaints being headache, palpitations, and breathlessness. Her heart was not clinically enlarged, her blood pressure was 230/180 mm Hg, and her eye grounds showed well marked arterial changes but no exudates or haemorrhages.

Her progress on the rice diet is shown in fig. 1. Her blood pressure fell from an average of 218/144 to 159/116. The lowest blood pressure reading before starting the diet was 217/135, the lowest while on the diet was 133/97. Her headaches vanished completely and she changed from being a depressed and miserable patient to a cheerful and active person up and about the ward. Standard cardiac radiographs suggested some diminution in heart size. Her blood urea fell from 30 to 24 mg per 100 ml, and her plasma-cholesterol from 206 to 145 mg per 100 ml. Her weight fell by 11 lb. The whole of the time she was on the diet she did not complain of headache.

Despite the striking relief of symptoms, the patient tired of the diet, and after fifty three days she was put on a low salt diet (15 g of sodium chloride per day). During the next four days her weight rose slightly and it appeared that

Fig. 1—Blood-pressure and weight-curves in case 1

her blood pressure was again rising. She returned home on a low salt régime, and when seen some three weeks later, although she was still free of headaches, a casual reading of her blood pressure was 246/155 mm Hg.

Case 2—A married woman, aged 59, had enjoyed good health till six months before admission to hospital, when she began to complain of headaches, which gradually became more severe, persisting throughout the day and making sleep impossible at night without large doses of analgesic and hypnotic drugs. She was found to have well marked hypertension, significant left-sided cardiac hypertrophy, and considerable retinal haemorrhages and exudates. The urine was free of albumin and casts, but the concentrating power of the kidney was impaired, giving a urea-clearance of only 30% of normal. During the ten-day observation period in the ward on a normal diet, the lowest recorded blood pressure was 180/120 mm Hg. During deep sleep under a hypnotic, it fell to 160/100.

She was treated with the rice diet for six weeks, being encouraged during this time to be out of bed for the greater part of the day. The blood pressure began to fall soon after treatment was started and reached its lowest level of 100/64 at the end of the fourth week (fig. 2). Headache disappeared during the second week, and she remained symptom free until the fifth week when she was given, while continuing

Fig. 2—Blood pressure and weight-curves in case 2, showing the effect of added sodium chloride.

the rice diet, 7.5 g a day of sodium chloride in capsules, she was unaware of their content. During this week her blood pressure rose sharply to 190/100, and this was associated with a gain in weight of 1 kg and a return of headache. During the sixth week, when the added salt was withheld, the blood pressure and body weight fell and the headache disappeared.

Reassessment of the case at the end of the rice-diet period showed decrease in the size of the heart and definite regression of the retinal changes. The urea-clearance was essentially unchanged. The blood urea nitrogen level had fallen from 13 mg to 6 mg per 100 ml. The patient was then given a low-salt diet containing 2 g of sodium chloride daily. The blood pressure showed a tendency to rise during the few days she was taking this diet in hospital. She continued to take it with scrupulous care as an outpatient, but when she reported four weeks later her blood pressure had risen to its initial hypertensive level (198/124).

Case 3—This patient was a man, aged 39, who was admitted in January, 1950. In 1929 he had an attack of acute nephritis and he was again in hospital in 1930 with haematuria and albuminuria. In 1939 he was rejected for military service on account of some abnormality in his urine. He kept well until one year before admission, when he started having headaches which later were associated with nausea and vomiting. One month before admission he noticed that vision in his left eye was blurred.

On admission he looked ill. Examination of his eye-grounds showed that while the discs were well-defined, there was pronounced narrowing of the arteries, arteriovenous nipping, scattered cotton wool exudates and occasional haemorrhages. Clinically his heart was not enlarged, his blood pressure

TABLE II—ANALYSIS OF 41 CASES TREATED

Type of case	Average diastolic blood pressure (mm Hg)				Total no of cases
	120 or over		110-120		
	Male	Female	Male	Female	
Benign essential hypertension	5	19	1	3	28
Malignant essential hypertension	4	2	—	—	6
Renal hypertension	5	1	—	1	7
Total	14	22	1	4	41

at least an hour 5 patients with somewhat lower original diastolic pressures were treated, but these are not included in the analysis of results Table II shows the types of case treated

RESULTS

The diet is unappetising and monotonous, and several patients (not included in table II) were unable to take it for more than a few days It can be made more palatable by careful preparation and presentation, and full cooperation between patient, doctor, and dietitian is required It had been hoped to maintain the diet in each case for at least six weeks The average period spent on the diet, in hospital, was forty one days, with a range of twenty to ninety-five days Patients more willingly persevere once subjective improvement has occurred, but, even so, most are anxious to have the diet altered or stopped before the end of six weeks In a few cases it was gradually modified by the addition of other foods (as recommended by Kempner), but it has not, so far, proved possible to persuade more than a few patients to continue on the diet outside hospital, and most went home on an ordinary low sodium diet

Of 33 patients with symptoms referable to hypertension, 25 (75%) obtained relief Headaches, which were present in 26, disappeared in all but 4, often within a few days of starting the diet

In the majority of patients, the resting blood pressure fell The change in blood pressure can best be appreciated from case histories and charts, but an analysis of the actual readings is given in table III This table shows the average fall in blood pressure recorded in 35 of the 36 patients whose average diastolic pressure during the control period was at least 120 mm Hg (The remaining patient died while on the diet) The comparison has been made between the average blood pressure reading over several days prior to the diet and the average of several days towards the end of the period on the diet The average fall of blood pressure in these 35 cases was 55/26 mm Hg, only 7 had a fall of less than 30 mm Hg in the systolic pressure, and only 8 a fall of less than 15 mm Hg in the diastolic pressure

In 24 patients a barbiturate sedation test was carried out before the diet was started In 10 of these, the daily blood pressure reading while on the diet fell below the minimum reading recorded during the test The

TABLE III—FALL OF BLOOD PRESSURE IN 35 CASES ON THE RICE DIET

Type of case	No of cases	Average fall of blood pressure (mm Hg)		Range of fall of blood pressure (mm Hg)	
		Systolic	Diastolic	Systolic	Diastolic
Benign essential hypertension	24	58	25	12-100	6-50
Malignant essential hypertension	6	51	29	23-76	10-46
Renal hypertension	5	49	27	29-80	15-37
All cases	35	55	26	—	—

test was repeated in 11 patients while still on the diet, and in 7 the blood-pressure fell to a level still lower than the daily reading

The blood pressure remained low so long as the rice diet was continued, but rose rapidly on changing to an ordinary low sodium diet, and within a few days or weeks, though symptomatic relief might persist, the blood pressure returned to its original level

The usual low sodium diet contains 1-3 g of sodium chloride in the twenty four hours 11 patients, without other modification of the rice diet, were given capsules containing sodium chloride (the patient usually having no knowledge of the content of the capsules) In 8 of these, the blood pressure rose

In 13 of the patients in whom the blood pressure fell, standard radiographs suggested that the heart size had diminished. Improvement in the electrocardiographic tracings and in the eye grounds occurred in only a few cases

All patients lost weight while on the diet This was readily explained in the 7 patients who had oedema, for this cleared rapidly on the low salt régime In the non oedematous patients, the average weight loss was 9 lb In some the weight tended to become stabilised, but in many there was a steady loss, suggesting that either the caloric or the protein intake was too low

Nitrogen balance studies were carried out in 3 patients (see case 3) Each of these was in a slightly negative

TABLE IV—BLOOD UREA (MG PER 100 ML) OF PATIENTS ON RICE DIET

Original level	No of cases	Averages	
		Before diet	Lowest reading on diet
10-40	24	28	23
41-80	3	40	27
Over 80	3	119	74

nitrogen balance at the end of five or six weeks on the diet To test the effect of protein on the blood pressure, calcium caseinate, which is almost sodium free, was added to the diet of 3 patients In no case did the addition of 40 g daily result in a rise of pressure

EFFECT ON BLOOD AND URINE CHEMISTRY

Except in occasional cases the plasma sodium remained within normal limits The plasma-chloride usually fell to the lower limit of normal or even a little below this The excretion of chloride in the urine usually became very low within a few days of starting the diet, and the urinary chloride, expressed as sodium chloride, fell below 300 mg per day Once the patient is stabilised on the diet, the urinary chloride can be used as a check that he is adhering to the régime

The sodium output also usually falls within two or three days to very low levels, often reaching only 50 mg in the twenty four hours, but the occasional patient with renal failure may be unable to control the loss in the urine, and this continuous drain may precipitate dangerous uræmic symptoms 2 patients with impaired renal function continued to excrete sodium in their urine, and one, a case of chronic nephritis, after initial improvement became rapidly worse and died from uræmia One other patient with chronic nephritis went home on a low sodium diet and returned two weeks later, his blood-urea having risen from 48 to 186 mg per 100 ml A similar dangerous loss of sodium may occur if mercurial diuretics are used to accelerate the loss of oedema in a patient on so low a sodium intake In one such case, the plasma sodium fell to 127 m eq per litre (normal 137-147) Quite apart, however, from

TABLE V—RENAL FUNCTION TESTS BEFORE AND DURING RICE DIET

Test	No of cases	Averages	
		Before diet	During diet
Urea-clearance	28	70 %	42.5 %
Urea-concentration test	4	3.5 g per 100 ml.	2.1 g per 100 ml
Endogenous-creatinine clearance	5	57 ml per min	46 ml per min
Inulin-clearance	3	64 ml per min	43 ml per min
Diodone-clearance	3	280 ml per min	251 ml per min

cases known to have renal insufficiency, there is substantial evidence that renal function becomes impaired while patients are on the rice diet.

As is to be expected on so low a protein intake, the blood urea fell in almost every case (table IV). This fall might account for some diminution in the power to produce a urine of high specific gravity, but could not explain the other changes in renal function tests (table V). Thus, in some cases a fall in the inulin and diodone clearances, in others a lowered endogenous creatinine clearance, and in yet others a fall in phenolsulphone phthalein excretion was observed. This impaired renal function seems to be reversible, as there was a prompt improvement when the rice diet was stopped.

The plasma protein level was well maintained on the diet. There was no consistent change in the plasma cholesterol, but, in general, patients with high original levels tended to show a considerable fall, while those with normal or low original figures showed little change. There was no correlation between fall in the plasma-cholesterol and fall of blood pressure.

ILLUSTRATIVE CASE-RECORDS

Case 1—A married woman, aged 42, was admitted to hospital with severe benign essential hypertension, her chief complaints being headache, palpitations, and breathlessness. Her heart was not clinically enlarged, her blood pressure was 230/160 mm. Hg, and her eye grounds showed well marked arterial changes but no exudates or haemorrhages.

Her progress on the rice diet is shown in fig 1. Her blood pressure fell from an average of 219/144 to 159/116. The lowest blood pressure reading before starting the diet was 217/135, the lowest while on the diet was 133/97. Her headaches vanished completely and she changed from being a depressed and miserable patient to a cheerful and active person up and about the ward. Standard cardiac radiographs suggested some diminution in heart size. Her blood urea fell from 30 to 24 mg per 100 ml, and her plasma-cholesterol from 206 to 145 mg per 100 ml. Her weight fell by 11 lb. The whole of the time she was on the diet she did not complain of headache.

Despite the striking relief of symptoms, the patient tired of the diet, and after fifty three days she was put on a low-salt diet (15 g of sodium chloride per day). During the next four days her weight rose slightly and it appeared that

Fig 1—Blood-pressure and weight-curves in case 1

her blood pressure was again rising. She returned home on a low salt régime, and when seen some three weeks later, although she was still free of headaches, a casual reading of her blood pressure was 246/155 mm Hg.

Case 2—A married woman, aged 59, had enjoyed good health till six months before admission to hospital, when she began to complain of headaches, which gradually became more severe, persisting throughout the day and making sleep impossible at night without large doses of analgesic and hypnotic drugs. She was found to have well marked hypertension, significant left-sided cardiac hypertrophy, and considerable retinal haemorrhages and exudates. The urine was free of albumin and casts, but the concentrating power of the kidney was impaired, giving a urea-clearance of only 30% of normal. During the ten-day observation period in the ward on a normal diet, the lowest recorded blood pressure was 180/120 mm Hg. During deep sleep under a hypnotic, it fell to 160/100.

She was treated with the rice diet for six weeks, being encouraged during this time to be out of bed for the greater part of the day. The blood pressure began to fall soon after treatment was started and reached its lowest level of 100/64 at the end of the fourth week (fig 2). Headache disappeared during the second week, and she remained symptom free until the fifth week when she was given, while continuing

Fig 2—Blood-pressure and weight-curves in case 2, showing the effect of added sodium chloride.

the rice diet, 7.5 g a day of sodium chloride in capsules, she was unaware of their content. During this week her blood pressure rose sharply to 190/100, and this was associated with a gain in weight of 1 kg and a return of headache. During the sixth week, when the added salt was withheld, the blood pressure and body weight fell and the headache disappeared.

Reassessment of the case at the end of the rice-diet period showed decrease in the size of the heart and definite regression of the retinal changes. The urea-clearance was essentially unchanged. The blood urea nitrogen level had fallen from 13 mg to 6 mg per 100 ml. The patient was then given a low salt diet containing 2 g of sodium chloride daily. The blood pressure showed a tendency to rise during the few days she was taking this diet in hospital. She continued to take it with scrupulous care as an outpatient, but when she reported four weeks later her blood pressure had risen to its initial hypertensive level (196/124).

Case 3—This patient was a man, aged 39 who was admitted in January, 1950. In 1929 he had an attack of acute nephritis and he was again in hospital in 1930 with haematuria and albuminuria. In 1939 he was rejected for military service on account of some abnormality in his urine. He kept well until one year before admission, when he started having headaches which later were associated with nausea and vomiting. One month before admission he noticed that vision in his left eye was blurred.

On admission he looked ill. Examination of his eye-grounds showed that, while the discs were well-defined, there was pronounced narrowing of the arteries, arteriovenous nipping, scattered cotton wool exudates, and occasional haemorrhages. Clinically his heart was not enlarged, his blood pressure

was 220/136 mm Hg. His urine contained a small amount of albumin. Chronic nephritis was diagnosed. Investigations showed that his blood urea was 108 mg per 100 ml, with a maximal urea clearance of 18%. His plasma proteins were within normal limits. In view of his raised blood urea it was felt that a low protein diet was indicated, and because of his severe hypertension and headaches it was decided to observe the effect of the rice diet.

He was unable to eat the full amount of rice. The effect of the diet on his blood pressure and his weight is shown in fig. 3. Within three days of starting the diet his headaches vanished. His blood pressure fell and reached a level of about 150/100. His blood urea fell to 60 mg per 100 ml on the tenth day of the diet and was only 72 mg per 100 ml after five weeks. A careful watch was kept on his urinary sodium output, which is also shown in fig. 3. It fell rapidly within three days of starting the diet and continued to fall during the first four weeks.

During the six weeks on the diet his eye grounds showed well marked improvement until only one exudate and one haemorrhage were visible. Serial electrocardiographs showed no change, but serial standard cardiac radiographs suggested that his heart had diminished in size, though it had been regarded originally as within normal limits. His plasma cholesterol remained unaltered at 155 mg per 100 ml, and his haemoglobin rose from 76% to 94% without the addition of iron to his diet. His plasma sodium was 135 meq per litre after thirty nine days on the diet.

After six weeks on the diet a nitrogen balance was carried out. During a four day period his daily nitrogen excretion averaged 3.14 g in the urine and 0.95 g in the faeces, giving a total of 4.09 g. Exact duplicates of the diet eaten on two of these days were analysed and contained 2.8 and 2.17 g of nitrogen respectively.

On the forty eighth day the diet was modified by the addition of a small quantity of meat, potatoes, salt-free bread and margarine, and 1 oz. of milk daily. It was clear that he would be unable to manage this diet at home, and on the sixty first day he was put on a low sodium diet containing about 500 mg of sodium, according to tables, and 67 g of protein. When he left hospital on the seventy second day his blood pressure had risen to 180/114, his blood urea was 132 mg per 100 ml, and there had been a slight recurrence of his headache.

Fig. 3—Blood-pressure, weight, blood urea and urinary sodium excretion in a case of chronic nephritis treated with the rice diet (case 3).

DISCUSSION

This short term trial of the rice diet has confirmed the claims made by Kempner. He reported (1948) that out of 500 patients treated with the diet for periods ranging from four to eight hundred and ninety eight days, 311 showed a fall in blood pressure which averaged 47 mm Hg systolic and 21 mm Hg diastolic. The average fall in 35 patients treated by us, over period ranging from twenty to ninety five days, was 55/26 mm Hg.

Kempner states that the blood pressure may fall within four days of starting the diet, though a fall may occur only after the diet has been continued for some months. He has produced impressive accounts of the continued health of patients who remained on the modified diet for long periods. Our experience would suggest that few patients, in this country, could be persuaded to stick strictly to the diet for much longer than six weeks, and further that the home use of the diet or its modification is not easy.

It is difficult to appreciate the reasoning which led Kempner to introduce the rice diet. Studies of the metabolism of kidney slices *in vitro*, in the Warburg apparatus, had convinced him (1938) of the importance of the surrounding media for normal cellular metabolism. In the belief that abnormal metabolism of damaged renal cells might be responsible for hypertension, he introduced his diet with the object of compensating renal metabolic dysfunction. Kempner claims that the diet contains a lower sodium, protein, and fat content than any low sodium, low protein, or low fat diet previously used in the treatment of hypertension, and he regards all these factors as important. Most workers, however, now believe that any fall of blood-pressure caused by the diet is the result of the extreme sodium restriction. In several of our cases the addition of sodium chloride to the diet led to a rise in blood pressure (see case 2 and fig. 2).

Low sodium diets have long been advocated in the treatment of hypertension, and the subject has recently been reviewed by Bang et al (1949). The results that may be expected and the dangers of this form of treatment were fully discussed by Allen and Sherrill as long ago as 1922. They reported that the blood pressure might fall in a few days or in several months, they regarded the diet as "salt-free" only when the urinary sodium chloride fell to 0.5 g or less per day, and they were well aware that in cases of severe nephritis the sudden withdrawal of salt might precipitate uraemia. Their immediate results were impressive, but the régime never became popular, probably because of the difficulty of persuading both doctors and patients of the necessity for such severe salt restriction.

It appears unlikely that protein restriction is an effective factor in the diet. Schroeder et al (1949) added unsalted meat to the diet of a patient on the rice régime, and we have observed the effect, in 3 patients, of adding 40 g of calcium caseinate (36 g protein) daily for two weeks. In no case did the diastolic blood pressure rise significantly. Bryant and Blecha (1947), using low sodium diets (200 mg per day) containing 70 g of protein and 80-175 g of fat, obtained results very similar to those of Kempner.

By estimating the urinary nitrogen and calculating the dietary nitrogen from tables, Kempner concluded that patients after three months on the rice diet were in nitrogen balance. He claimed that the high caloric intake spared protein metabolism. His results have been refuted by Schwartz and Merlis (1948) and by Currens et al (1949), but confirmed by his co-workers Peschel and Peschel (1950). The 3 patients investigated by us were still in slightly negative nitrogen balance at the end of six weeks. In 2 cases followed throughout

their period on the diet, the original negative balance became gradually less pronounced. The progressive loss of weight observed in most of our patients may be related to this negative nitrogen balance, to an insufficient caloric intake, or to loss of oedema.

Brozek et al (1948) have reviewed the effect of starvation on hypertension, and suggest that a drastic restriction of caloric intake may be as effective as sodium restriction in lowering blood-pressure. We have observed a steady fall of blood pressure in patients who maintained their weight after an initial fall during the first few days, so that inanition is unlikely to have been an important factor. Similar observations have been made by Flipse and Flipse (1947). The low fat content of the rice diet is presumably responsible for the fall in the plasma-cholesterol in those patients who have an initially high level, but we have found no correlation between fall in blood-cholesterol and fall in blood pressure.

Finally, it has been claimed that much of the effect produced by the diet is psychological (Ayman 1949) or is the result of rest after an inadequate period of controlled observation (Schroeder 1948). We are satisfied that these factors cannot fully explain our results. Many of our patients were ambulant during treatment, and we have twice observed a satisfactory response to the diet when a thoracolumbar splanchnicectomy had failed to produce a sustained fall of pressure.

The danger of the diet requires emphasis. Fatal uræmia during treatment has been reported by Schroeder (1948), and we have observed such a case. If, in non-oedematous patients, the urinary sodium or chloride does not fall to a low level within a few days of starting the diet, the blood urea and blood sodium must be carefully observed.

Impairment of renal function, while on the diet, has been reported (Weston et al 1948, Chasis et al 1949, 1950, Currans et al 1949), and we have confirmed this. The glomerular filtration rate is affected to a greater extent than is tubular reabsorption. A similar reduction in glomerular function was noted by McCance (1936) in his experiments on salt deprivation in normal man, and Chasis et al (1950) found that the decrease in glomerular filtration rate was abolished by the addition of sodium chloride to the diet. The fall in maximal tubular reabsorption of *p*-aminoluppurate was not improved by sodium chloride, but the level returned to normal on a mixed diet.

The rice diet is of great experimental interest, for it may help to throw new light on the relationship of sodium chloride to hypertension, and it provides an elimination diet to which substances may be added to test their effect on the blood pressure. We believe that the Kempner rice diet can be expected to produce a considerable fall in blood pressure in about 70% of patients with either renal or essential hypertension, provided that they adhere strictly to the régime. This fall is often accompanied by great symptomatic relief. Clearly, however, it is extremely difficult for patients to continue on the diet for more than two months, and as soon as the sodium-chloride intake is increased even slightly the blood pressure is likely to rise again. It appears, therefore, that this régime will not become a popular form of therapy.

Our thanks are due to the Ministry of Food who kindly provided much of the rice and sugar used in this investigation. The study could not have been carried out without the wholehearted assistance of our ward sisters and dietitians. We also acknowledge most gratefully the help of our colleagues, and in particular Dr P. Arnold (U.C.H.), Dr Trevor Kinnear, and Dr S. Lopus (Edinburgh), Dr G. E. Milne (Manchester), and Dr A. M. Blackstock and Mr J. H. Blackburn (York).

It is generally accepted that in the smallpox patient virus is distributed to the skin by the blood stream at or just before the onset of illness. The clinical course of the illness and histological observations on the skin lesions support this view, and in ectromelha, the natural pox disease of mice, a similar dissemination of virus to the skin occurs (Fenner 1948). The viraemia in smallpox has not been studied by the isolation of virus from cases, although Downie and Dumbell (1947) isolated virus from the blood of a hæmorrhagic case on the fifth day of illness.

A sensitive method for the detection of variola virus is provided by inoculation of material on the chorio-allantois of developing chick embryos, in this tissue variola virus produces in three days very characteristic lesions which are readily distinguishable from those produced by other viruses. The infrequent occurrence of smallpox in this country offers few opportunities for studies of this kind, and, as cases are not often diagnosed before the focal rash appears, material from the pre-eruptive stage of illness is seldom available. However, we have recently been able to make a few observations on the viraemia in the early stage of the disease and these are reported below. For specimens from cases in the Glasgow outbreak of 1950 we are indebted to Dr N. R. Grist of Knightswood Fever Hospital.

METHODS

All specimens of blood were collected by venepuncture and allowed to clot. From three patients blood serum was tested and from two of these blood cells from the clot were also examined separately by inoculation on to the chorio-allantois. In later cases the small samples of clotted blood were lysed by the addition of equal volumes of sterile distilled water and the lysed specimens examined. Approximately 0.1 ml was inoculated into each egg, two to four eggs being used for each specimen. After three days further incubation the

was 220/136 mm Hg. His urine contained a small amount of albumin. Chronic nephritis was diagnosed. Investigations showed that his blood urea was 108 mg per 100 ml, with a maximal urea clearance of 18%. His plasma proteins were within normal limits. In view of his raised blood urea it was felt that a low protein diet was indicated, and because of his severe hypertension and headaches it was decided to observe the effect of the rice diet.

He was unable to eat the full amount of rice. The effect of the diet on his blood pressure and his weight is shown in fig 3. Within three days of starting the diet his headaches vanished. His blood pressure fell and reached a level of about 150/100. His blood urea fell to 60 mg per 100 ml on the tenth day of the diet and was only 72 mg per 100 ml after five weeks. A careful watch was kept on his urinary sodium output, which is also shown in fig 3. It fell rapidly within three days of starting the diet and continued to fall during the first four weeks.

During the six weeks on the diet his eye grounds showed well marked improvement until only one exudate and one hemorrhage were visible. Serial electrocardiographs showed no change, but serial standard cardiac radiographs suggested that his heart had diminished in size, though it had been regarded originally as within normal limits. His plasma cholesterol remained unaltered at 155 mg per 100 ml, and his hemoglobin rose from 76% to 94% without the addition of iron to his diet. His plasma sodium was 135 meq per litre after thirty nine days on the diet.

After six weeks on the diet a nitrogen balance was carried out. During a four day period his daily nitrogen excretion averaged 3.14 g in the urine and 0.95 g in the faeces, giving a total of 4.09 g. Exact duplicates of the diet eaten on two of these days was analysed and contained 2.8 and 2.17 g of nitrogen respectively.

On the forty eighth day the diet was modified by the addition of a small quantity of meat, potatoes, salt-free bread and margarine, and 1 oz of milk daily. It was clear that he would be unable to manage this diet at home, and on the sixty first day he was put on a low sodium diet containing about 500 mg of sodium, according to tables, and 67 g of protein. When he left hospital on the seventy second day his blood pressure had risen to 180/114, his blood urea was 132 mg per 100 ml, and there had been a slight recurrence of his headache.

Fig 3—Blood pressure, weight, blood urea, and urinary sodium excretion in a case of chronic nephritis treated with the rice diet (case 3).

DISCUSSION

This short term trial of the rice diet has confirmed the claims made by Kempner. He reported (1948) that out of 500 patients treated with the diet for periods ranging from four to eight hundred and ninety eight days, 311 showed a fall in blood pressure which averaged 47 mm Hg systolic and 21 mm Hg diastolic. The average fall in 35 patients treated by us, over periods ranging from twenty to ninety five days, was 55/26 mm Hg.

Kempner states that the blood pressure may fall within four days of starting the diet, though a fall may occur only after the diet has been continued for some months. He has produced impressive accounts of the continued health of patients who remained on the modified diet for long periods. Our experience would suggest that few patients, in this country, could be persuaded to stick strictly to the diet for much longer than six weeks, and further that the home use of the diet or its modification is not easy.

It is difficult to appreciate the reasoning which led Kempner to introduce the rice diet. Studies of the metabolism of kidney slices *in vitro*, in the Warburg apparatus, had convinced him (1938) of the importance of the surrounding media for normal cellular metabolism. In the belief that abnormal metabolism of damaged renal cells might be responsible for hypertension, he introduced his diet with the object of compensating renal metabolic dysfunction. Kempner claims that the diet contains a lower sodium, protein, and fat content than any low sodium, low protein, or low fat diet previously used in the treatment of hypertension, and he regards all these factors as important. Most workers, however, now believe that any fall of blood pressure caused by the diet is the result of the extreme sodium restriction. In several of our cases the addition of sodium chloride to the diet led to a rise in blood pressure (see case 2 and fig 2).

Low sodium diets have long been advocated in the treatment of hypertension, and the subject has recently been reviewed by Bang et al (1949). The results that may be expected and the dangers of this form of treatment were fully discussed by Allen and Sherrill as long ago as 1922. They reported that the blood pressure might fall in a few days or in several months, they regarded the diet as "salt free" only when the urinary sodium chloride fell to 0.5 g or less per day, and they were well aware that in cases of severe nephritis the sudden withdrawal of salt might precipitate uraemia. Their immediate results were impressive, but the régime never became popular, probably because of the difficulty of persuading both doctors and patients of the necessity for such severe salt restriction.

It appears unlikely that protein restriction is an effective factor in the diet. Schroeder et al (1949) added unsalted meat to the diet of a patient on the rice régime, and we have observed the effect, in 3 patients, of adding 40 g of calcium caseinate (36 g protein) daily for two weeks. In no case did the diastolic blood pressure rise significantly. Bryant and Blecha (1947), using low sodium diets (200 mg per day) containing 70 g of protein and 80-175 g of fat, obtained results very similar to those of Kempner.

By estimating the urinary nitrogen and calculating the dietary nitrogen from tables, Kempner concluded that patients after three months on the rice diet were in nitrogen balance. He claimed that the high caloric intake spared protein metabolism. His results have been refuted by Schwartz and Merlis (1948) and by Currens et al (1949), but confirmed by his co-workers Peschel and Peschel (1950). The 3 patients investigated by us were still in slightly negative nitrogen balance at the end of six weeks. In 2 cases followed throughout

the chorio allantoic membrane of the developing hen's egg as a culture medium provided a cheaper and more sensitive method, and, as variola and vaccinia produce different macroscopic lesions in this site, it also provides specific differential diagnosis

SMEARS

From their experience in the Middle East, where smallpox was endemic, van Rooyen and Illingworth (1944) emphasised the value of the microscopical examination of stained smears of scrapings from papules and the base of vesicles. Though this method is valuable under certain conditions, we consider it less reliable in this country, where smallpox may be seen only at intervals of two years or more, and the smears may have to be made by persons unpractised in the technique and not possessing the essential thoroughly clean glass slides. At the same time, the repeal of the law for compulsory vaccination in England in July, 1948, increased the importance of the laboratory diagnosis in the early stages as an aid to the control of smallpox. Further investigation has shown that, in moderately severe cases, enough material may be obtained by scraping 3 or 4 macules or papules with a scalpel or needle and transferring this to four clean glass slides to provide an antigen which will give a positive reaction with a hyperimmune vaccinia rabbit serum in the complement-fixation test. The result of this test is obtained within 24 hours of receipt of the specimens in the laboratory, hence a positive diagnosis may be given before the rash has reached the vesicular stage in the patient. If less material than this is obtained, a negative complement fixation test is of doubtful significance, and, until more information is available, reliance must be placed on the egg culture, from which an answer cannot be obtained for 48-72 hours. A negative result on the larger amount of material is also only presumptive, and the final diagnosis depends on the egg culture.

In this early stage the ideal material for the laboratory is six good smears: one for microscopical examination, four for antigen for the complement fixation test, and one for egg culture. The use of smears is emphasised because the tests chosen depend entirely on the quantity of material, and the amount of material obtained from the rash at the maculopapular stage can most readily be judged by this method. If the lesions are scraped with a needle, this also should be sent to the laboratory. In the vesicular or pustular stage, the fluid should be removed from 6-10 lesions into capillary tubes, and smears should be made from scrapings of the base of the lesion. In the healing stage, crusts or tops of 10-12 lesions should be collected.

Results of complement-fixation tests on skin scrapings of Mr H, Miss F, Miss W, and Mrs R are shown in table 1. In the case of Miss B an extract, in 0.7 ml of saline solution, of three smears which had been stored for 13 months in a petri dish in the ice box at $+4^{\circ}\text{C}$ still showed plaques on egg culture and gave a positive complement fixation test.

The following two case records illustrate the type of circumstance where the laboratory can be of help.

Mr E M, aged 30 had been vaccinated in infancy (scar present) in 1941 unsuccessfully, and 6 days before admission, with mild positive reaction, on April 8 1949. 4 days before admission he had had slight feverishness, aching limbs, nasal catarrh, and pyrexia (100°F), followed by the development of 4-5 pinpoint pustules on scapula and upper shoulders. On admission he felt well. In 48 hours these lesions cleared, to be succeeded in 3 days by 2-3 similar lesions with pustulation only. From these subsequent lesions egg culture was positive for variola. Finally negative scrapings from the areas which had been the site of lesions were obtained 13 days after admission.

Mr R B, aged 23, had been vaccinated at the age of 18 (scar present) at the age of 20 unsuccessfully, and 8 days before admission, with a marked reaction, on April 10 1949.

He had had slight malaise 4 days before admission, followed by the appearance of 3-4 papular pustules on the back and chest, scrapings of which were positive for variola on egg culture.

These two cases of smallpox were modified by past vaccination to a degree that would have rendered them dismissible as furunculosis or minor sepsis apart from their presence in *ss Mooltan*. In Mr E M a secondary crop of abortive lesions developed after the initial ones had cleared, pustulation occurring on the 4th and 7th days after an initial febrile illness and on the same site—the shoulders. Presumably pustulation can occur without evidence of any initial symptoms of malaise in a highly vaccinated person, and one might wonder what degree of scrutiny in the circumstances is necessary for passengers leaving an infected ship. What is perhaps essential is that all suspicious skin lesions in contacts should be examined by egg culture and complement fixation, and that in interpreting the word "suspicious" the very high degree of modification which can occur in the presence of partial immunity to smallpox should be borne in mind.

VIRUS IN BLOOD

The extreme sensitivity of the egg culture for variola virus suggested that we might apply the method to obtain information about the pathogenesis of smallpox and its infectious period. Blood, nose and throat swabs, and skin scrapings were collected from many of the patients who developed smallpox as a result of the case in *ss Mooltan* in April, 1949. Table 1 shows that virus was recovered from the blood of only two patients. Both cases were of rapidly fatal haemorrhagic smallpox in which the macules were essentially petechial and few. The virus was recovered from Mrs A. on the day of onset of the diffuse erythematous rash, which was the 3rd day of symptoms and the day before death, and from Miss F (see figure) on the day of onset of the erythematous rash, which was the 3rd day of symptoms and within 1 hour of observation of the first macules (she died about 12 hours later). Miss F had only 2 lesions on the face and 6 on the abdomen, from which the smears were made for the complement-fixation test and culture. In six other patients cultures of serum and clot were negative: (a) on the day of onset of illness in one patient, (b) on the day of onset of rash in two patients, and (c) on the 2nd day in one patient, the 3rd in two and the 4th in one patient. All negative chorio allantoic membranes were passed once more and remained negative. This suggests that the viraemia is only transitory. Although Mrs R had never been vaccinated and died on the 15th day from onset, serum taken on the 5th day of illness neutralised a small amount of virus. In the other

Growth on chorio-allantoic membrane of variola virus from 0.1 ml. of serum of Miss F collected on first day of rash

DEMONSTRATION OF VIRUS IN THE BLOOD OF SMALLPOX PATIENTS

Case no	Sex and age in years	Day of illness	Infective units virus in 0.1 ml blood	Nature and extent of rash
1	M 35	5	2 (cells) 5 (serum)	Hæmorrhagic (died 8 days)
2	M 15	1 2 3	1 0 0	Moderate, discrete
3	M 36	1	0 (serum)	Modified sparse
4	F 20	1	0	Confluent (died 18 days)
5	M 51	2	0	Modified sparse
6	F 11 ^{1/2}	3	2	Modified, sparse (died 8 days)
7	F 17	2 3 4	1 51 7	Confluent, hæmorrhagic (died 10 days)

eggs were opened and the chorio allantois examined for the presence of visible lesions. Lesions were counted and their nature confirmed by subinoculation of the ground up membranes into more eggs and by histological examination. If no lesions were visible on the membranes they were removed, ground with broken glass, and suspended in broth, and the supernatant fluid was inoculated on the chorio allantois of chick embryos. If, after three days, these showed no visible virus lesions the result was considered negative.

FINDINGS

The findings in individual cases are shown in the accompanying table.

Case 1 was a petty officer on board a ship returning to Liverpool from Bombay in 1946 (Pierce 1947). The findings in this case have already been reported (Downie and Dumbell 1947).

Case 2, the brother of a boy who contracted an infection in the laboratory, was under close medical supervision at the time of onset of his illness.

No lesions were seen on the chorio allantois in three eggs inoculated with blood taken on the first day of his illness, but these membranes when ground up and inoculated on two further eggs produced numerous typical lesions. Specimens taken on the second and third days of illness remained negative on passage. This boy had been successfully vaccinated eight days before his illness, but neutralising antibody to variola virus could not be detected in his blood-serum taken on the first and third days of illness. Swabs taken from this patient's throat on the first and second days were examined for virus, the swabs were extracted with a small amount of broth, and penicillin and streptomycin were added to the extract before it was inoculated on to the chorio allantois of 12-day chick embryos. After three days no lesions were seen on the membranes, which failed to produce variola infection on further passage. On the third day of illness when a faint macular rash was present on the face there were eight well developed lesions on the dorsum of the patient's tongue, but a swab was not taken from the throat at this time, when virus was certainly present.

The last five patients from whom specimens of blood or serum were available were infected in the Glasgow outbreak (Laidlaw and Horne 1950). Case 4 had not been successfully vaccinated and suffered from a fatal infection with confluent rash, but virus was not isolated from 0.2 ml. of blood collected on the third day of illness. Case 6 was an unvaccinated child suffering from congenital toxoplasmosis. It will be noted that in case 7 the amount of virus in the blood apparently diminished from the second to the fourth day.

DISCUSSION

The findings summarised in the table indicate that virus can be detected in the blood in the pre-eruptive stage of smallpox, particularly in severe infections. Even in these cases, however, it would seem that the virus diminishes in amount after the first few days of illness. That antibody in the blood is not necessarily responsible for the disappearance of virus is suggested by the absence of antibody on the third day of illness in case 2 who had been successfully vaccinated eight days before he became ill. It seems likely that in the average case of smallpox

antibody appears at the time when the rash is vesicular, the temperature falls and the general of the patient improves. We have, however, made observations at this critical period although we have been able to demonstrate antibody in the serum in cases after eight to ten days' illness. Although we have no data on the time of appearance of viraemia in relation to the onset of illness, it seems unlikely that there is general dissemination of virus to the skin before the temperature rises. The observations of Dixon (1948) on intra uterine infection in smallpox suggest "that transplacental infection occurs during the pre-eruptive fever and not before".

The only other finding which seems to call for comment was the failure to isolate virus from swabs in case 2 on the first and second days of illness. If these findings, relating only to one case, should be confirmed they would support the view held by some epidemiologists (Stallybrass 1949) that many cases of smallpox, although not all, do not become infectious until the focal eruption appears, at which time lesions in the mouth and pharynx are beginning to break down and discharge virus. This view, which is supported by the observations of MacCallum et al (1950), might explain in part the absence of a third wave of cases in the 1950 Glasgow outbreak. In this outbreak the secondary cases occurred in hospital contacts and were promptly diagnosed and isolated in the early stages of their disease, perhaps before they had become highly infectious.

SUMMARY

Smallpox virus was isolated from the blood during the first few days of illness in four of seven patients from whom blood was examined. Of these four patients three subsequently died of their infection. From these observations it would appear that virus is most likely to be found in the blood in the first days of the pre-eruptive fever. Virus was not detected in throat-swabs taken from a moderately severe case on the first and second days of illness.

UNTIL quite recently the laboratory diagnosis of smallpox consisted mainly in (1) a complement fixation test using a positive vaccinia rabbit serum to detect antigen in vesicle or pustule contents or crusts, and (2) culture of the virus from similar sources on to the scarified cornea of a rabbit's eye. The complement fixation test will not distinguish between variola and vaccinia, but separates both from chickenpox. In most laboratories the rabbit cornea culture method was successful in only about 50% of cases and again did not distinguish between the two viruses. The introduction of

chorio allantoic membrane of the developing hen's egg as a culture medium provided a cheaper and more sensitive method, and, as variola and vaccinia produce different macroscopic lesions in this site, it also provides specific differential diagnosis

SMEARS

From their experience in the Middle East, where smallpox was endemic, van Rooyen and Illingworth (1944) emphasised the value of the microscopical examination of stained smears of scrapings from papules and the base of vesicles. Though this method is valuable under certain conditions, we consider it less reliable in this country, where smallpox may be seen only at intervals of two years or more, and the smears may have to be made by persons unpractised in the technique and not possessing the essential thoroughly clean glass slides. At the same time, the repeal of the law for compulsory vaccination in England in July, 1948, increased the importance of the laboratory diagnosis in the early stages as an aid to the control of smallpox. Further investigation has shown that, in moderately severe cases, enough material may be obtained by scraping 3 or 4 macules or papules with a scalpel or needle and transferring this to four clean glass slides to provide an antigen which will give a positive reaction with a hyperimmune vaccinia rabbit serum in the complement-fixation test. The result of this test is obtained within 24 hours of receipt of the specimens in the laboratory, hence a positive diagnosis may be given before the rash has reached the vesicular stage in the patient. If less material than this is obtained, a negative complement fixation test is of doubtful significance, and, until more information is available, reliance must be placed on the egg culture, from which an answer cannot be obtained for 48-72 hours. A negative result on the larger amount of material is also only presumptive, and the final diagnosis depends on the egg culture.

In this early stage the ideal material for the laboratory is six good smears: one for microscopical examination, four for antigen for the complement fixation test, and one for egg culture. The use of smears is emphasised because the tests chosen depend entirely on the quantity of material, and the amount of material obtained from the rash at the maculopapular stage can most readily be judged by this method. If the lesions are scraped with a needle, this also should be sent to the laboratory. In the vesicular or pustular stage, the fluid should be removed from 6-10 lesions into capillary tubes, and smears should be made from scrapings of the base of the lesion. In the healing stage, crusts or tops of 10-12 lesions should be collected.

Results of complement-fixation tests on skin scrapings of Mr H., Miss F., Miss W., and Mrs R. are shown in table 1. In the case of Miss B. an extract in 0.7 ml. of saline solution of three smears which had been stored for 13 months in a petri dish in the ice box at $\pm 4^{\circ}\text{C}$ still showed plaques on egg culture and gave a positive complement fixation test.

The following two case-records illustrate the type of circumstance where the laboratory can be of help.

Mr E. M. aged 30 had been vaccinated in infancy (scar present) in 1941 unsuccessfully, and 6 days before admission, with mild positive reaction, on April 8 1949. 4 days before admission he had had slight feverishness aching limbs nasal catarrh and pyrexia (100°F), followed by the development of 4-5 pinpoint pustules on scapula and upper shoulders. On admission he felt well. In 48 hours these lesions cleared, to be succeeded in 3 days by 2-3 similar lesions with pustulation only. From these subsequent lesions egg culture was positive for variola. Finally negative scrapings from the areas which had been the site of lesions were obtained 13 days after admission.

Mr R. B. aged 23 had been vaccinated at the age of 18 (scar present) at the age of 20 unsuccessfully and 8 days before admission, with a marked reaction on April 10 1949.

He had had slight malaise 4 days before admission, followed by the appearance of 3-4 papular pustules on the back and chest, scrapings of which were positive for variola on egg culture.

These two cases of smallpox were modified by past vaccination to a degree that would have rendered them dismissible as furunculosis or minor sepsis apart from their presence in *s.s. Mooltan*. In Mr E. M. a secondary crop of abortive lesions developed after the initial ones had cleared, pustulation occurring on the 4th and 7th days after an initial febrile illness and on the same site—the shoulders. Presumably pustulation can occur without evidence of any initial symptoms of malaise in a highly vaccinated person, and one might wonder what degree of scrutiny in the circumstances is necessary for passengers leaving an infected ship. What is perhaps essential is that all suspicious skin lesions in contacts should be examined by egg culture and complement-fixation, and that in interpreting the word "suspicious" the very high degree of modification which can occur in the presence of partial immunity to smallpox should be borne in mind.

VIRUS IN BLOOD

The extreme sensitivity of the egg culture for variola virus suggested that we might apply the method to obtain information about the pathogenesis of smallpox and its infectious period. Blood, nose and throat swabs, and skin scrapings were collected from many of the patients who developed smallpox as a result of the case in *s.s. Mooltan* in April, 1949. Table 1 shows that virus was recovered from the blood of only two patients. Both cases were of rapidly fatal haemorrhagic smallpox in which the macules were essentially petechial and few. The virus was recovered from Mrs A. on the day of onset of the diffuse erythematous rash, which was the 3rd day of symptoms and the day before death, and from Miss F. (see figure) on the day of onset of the erythematous rash, which was the 3rd day of symptoms and within 1 hour of observation of the first macules (she died about 12 hours later). Miss F. had only 2 lesions on the face and 6 on the abdomen, from which the smears were made for the complement-fixation test and culture. In six other patients cultures of serum and clot were negative: (a) on the day of onset of illness in one patient, (b) on the day of onset of rash in two patients, and (c) on the 2nd day in one patient, the 3rd in two and the 4th in one patient. All negative chorio allantoic membranes were passed once more and remained negative. This suggests that the viraemia is only transitory. Although Mrs R. had never been vaccinated and died on the 15th day from onset, serum taken on the 5th day of illness neutralised a small amount of virus. In the other

Growth on chorio-allantoic membrane of variola virus from 0.1 ml. of serum of Miss F. collected on first day of rash.

patients, most of whom had been vaccinated or revaccinated from 35 years to 7 days before the collection of blood, neutralising antibody might have masked any circulating virus at the time of testing, although it appeared too late and was of insufficient strength to prevent viraemia, illness, and death.

The serum of Miss F, when first tested after 5 months' storage at +4°C, had 50 living virus particles per 0.1 ml. After it had been heated at 58°C for 30 minutes in a water-bath, no virus was detected, but the serum gave a positive reaction to a dilution of 1/320 when tested as antigen in the complement fixation test against a positive vaccinia serum. No neutralising antibodies for vaccinia or variola were detected in this heated serum, although the patient had been vaccinated 7 days earlier. This suggests that the blood of previously unvaccinated smallpox contacts might be examined in the pre-eruption stage for antigen in the complement fixation test, as well as for virus in egg culture, so as to obtain an earlier diagnosis.

VIRUS IN NOSE AND THROAT SWABS

It is unanimously agreed that virus is present in crusts and the last "seeds" from smallpox lesions, and the virus has been shown to survive for a long time in such material away from the body. Scott and Simon (1923), using a scarified rabbit corner, reported isolation of variola virus from nasopharyngeal secretions collected on the 23rd and 31st day of disease in two patients, when the skin lesions had already disappeared in each case. Similar results were reported by Friedemann and Gins (1917). We have not found any further satisfactory reports confirming their results, and did not examine material after the skin lesions had cleared. These findings are not supported by epidemiological observations and have been disregarded in quarantine regulations.

Arising out of these investigations is the question when and why patients are infectious in the early stages of smallpox. Although in a few countries patients are considered to be infectious in the incubation period,

almost all workers consider that infectivity is greater in the pre-eruption period and during the first appearance of the rash. Cases are on record of infection contracted from patients who died before they developed a focal eruption, but one wonders whether oral lesions were looked for in these cases. With this in mind, we thought it would be relatively easy to recover virus from nose and throat swabs or garglings. To our surprise we obtained the results seen in table I. Positive results were obtained only in two patients: one on the 2nd day of the rash, and one on the 3rd day, when ulcerating lesions were probably present in the mouth. Garglings and nose and throat swabs collected from two patients 4 and 3 days before the appearance of rash, from one patient 1 day before, two on the same day as the first rash, two on the 2nd day, and one on the 3rd day of rash, were all negative. All negative membranes received another passage and were negative. A very small amount of virus was recovered from a swab inserted through a cannula into the lung of Mrs. A after death, this might have been due to contamination from blood or skin during manipulation. (These results are in marked contrast to the 50% recovery rate of poliomyelitis virus from the pharynx of patients in the early stages of that disease, the comparatively insensitive monkey being used for test culture.) The egg culture was capable of detecting 2-3 living virus particles, hence these patients with negative cultures were either not excreting virus at all or were doing so only intermittently. Possibly some inactivator may be present in some salivary secretions. None of these patients gave rise to known secondary cases except Mrs. B who infected her husband and their daughter, both of whom were unvaccinated at the time of exposure.

DISCUSSION

How can we interpret these results in relation to infectivity of the patient in the early stage of smallpox? When variola was inoculated intradermally for vaccination in the pre-Jenner vaccination period, the incubation

Serum of Miss F when tested after storage for 16½ months at 4°C contained no haemagglutinin for vaccinia susceptible fowl erythrocytes but had an inhibitor titre of 1:8 against four haemagglutinating doses of vaccinia, using 0.5% cells and 0.1 ml. unit volumes

period was only 7–8 days. In monkeys a clinical illness simulating variola inoculata was seen when the virus was inoculated into the skin or mucosa of the mouth or trachea (Councilman et al. 1905). This can rarely happen in natural variola infection in man, but is seen in Kaposi's varicelliform eruption of vaccinal origin and in generalised vaccinia after primary vaccination, which resembles ectromelia or mousepox. Thus, although Fenner (1948) has suggested that experimental ectromelia might be studied to learn more of the pathogenesis of the acute exanthemata, it is not the ideal model. It is generally believed, and we agree, that the variola virus is usually inspired into the lung, where the primary focus or lesion develops. Possibly such a lesion usually breaks through into the capillaries but sometimes also externally, virus being emptied into the bronchi, and thus a large amount of virulent virus is expelled in a relatively short time in the febrile pre exanthem period. In a large proportion of cases, however, this does not happen, and the patient only becomes infectious when, as a result of the viraemia, lesions appear on the palate, tongue, pharyngeal, or buccal mucosa. These then break down, and virus is freed into the oral cavity.

The work of Councilman et al. (1905) seems to support our hypothesis. First, they found no primary lesion or protopustule in the trachea of fifty two fatal cases of human smallpox, and in their experiments on monkeys they only produced a disease resembling variola when dried powdered pustular material inserted in a tube past the larynx was inspired into the finer bronchi. Two of the five monkeys thus inoculated developed pneumonia. None of five that received dried crusts by the same method developed any signs of illness. This seems one possible explanation of the fact that some patients appear to have caused multiple infections in a short time before the appearance of their rash, whereas others have had a large number of contacts up to the second day of rash without causing any obvious secondary cases. Perhaps inspired virus might lodge in traumatised mucosa of the pharynx, larynx, or trachea and cause a primary lesion there, which might be a source of infection as well as a source of viraemia.

An example of lack of infection in possibly susceptible contacts to a severe case is the case of Miss F (table II). In the house where she stayed she was in close contact with three elderly persons, of whom at least two had not been vaccinated for 35–55 years and were in a susceptible state, as indicated by their reaction to revaccination although their sera contained some neutralising antibody by the fourth day after revaccination. Although Miss F was potentially highly infectious, with a very large amount of virus circulating in the blood and in the skin, no virus was recovered from her nose and throat, and no secondary cases arose. Blood and

nose and throat swabs were collected from the four household contacts on the 4th, 5th, 8th, and 11th days after onset of rash in Miss F and examined for virus with negative results.

Similar results were observed and obtained in connection with household contacts of Mr H and Mr W (table I), who were not removed from their environment until after the appearance of the rash.

Another possibility concerning the pathogenesis of smallpox is that virus passes from the nose and throat in the lymph to the adjacent lymph glands, where it multiplies before passing to the blood stream and thus to the lung and spleen. The virus may further multiply in the spleen, which then sheds virus into the blood stream for the true viraemia, as suggested by Fenner (1948) in ectromelia.

SUMMARY

Varicella virus has been recovered by egg culture from the blood in two rapidly fatal cases of smallpox on the day before and the day of onset of the discrete rash.

The virus was not recovered from the blood of five other patients during the first few days of the rash.

The virus was recovered from a throat swab collected on the 2nd day of the rash in one patient and the 3rd day in another. Single nose and throat cultures were negative in eight other patients during the pre eruption stage or first few days of the exanthem.

The results of these investigations emphasise the value of early recognition, particularly in the maculopapular stage, and isolation of suspected smallpox patients. Although we have failed to recover virus from the nose and throat of a few patients in the febrile pre eruption stage and first few days of rash, incontrovertible epidemiological evidence indicates that some patients are infectious at that stage. A possible explanation for this is discussed.

As no satisfactory antibiotic has yet been found for these viruses, gamma globulin, prepared from the serum of recently vaccinated persons or convalescent smallpox patients, should be given to household contacts who have not been vaccinated or have only been vaccinated in infancy long ago.

EFFECT OF CORTISONE ON EARLY FIBROSIS OF THE LIVER IN RATS

K ATERMAN

M.D., M.R.C.P., D.C.H.

COMMONWEALTH FELLOW, UNIVERSITY OF CHICAGO

In a study of the regeneration of the liver of rats, it was thought desirable to see whether 'Cortisone' can influence the process of experimentally induced hepatic fibrosis. If there were any such influence it might be expected to shed light on the relations of connective tissue and the regenerative capacity of hepatic cells. It was also hoped to define more clearly the remarkable effects of cortisone, particularly since the liver is a most favourable site for such an analysis. This follows from the relative simplicity of hepatic sinusoids, consisting as they do of but one type of cell (sinusoidal cell) and a basement membrane of ground substance in which is embedded but one type of fibre (reticular).

MATERIAL AND METHODS

Twenty female Sprague Dawley rats, weighing about 125 g, were fed *ad lib* with Purina chow. They were injected with carbon tetrachloride according to the schedule of Cameron and Karunaratne (1936). Data on

patients, most of whom had been vaccinated or revaccinated from 35 years to 7 days before the collection of blood, neutralising antibody might have masked any circulating virus at the time of testing, although it appeared too late and was of insufficient strength to prevent viraemia, illness, and death.

The serum of Miss F, when first tested after 5 months' storage at +4°C, had 50 living virus particles per 0.1 ml. After it had been heated at 58°C for 30 minutes in a water-bath, no virus was detected, but the serum gave a positive reaction to a dilution of 1/320 when tested as antigen in the complement fixation test against a positive vaccinia serum. No neutralising antibodies for vaccinia or variola were detected in this heated serum, although the patient had been vaccinated 7 days earlier. This suggests that the blood of previously unvaccinated smallpox contacts might be examined in the pre-eruption stage for antigen in the complement fixation test, as well as for virus in egg culture, so as to obtain an earlier diagnosis.

VIRUS IN NOSE AND THROAT SWABS

It is unanimously agreed that virus is present in crusts and the last "seeds" from smallpox lesions, and the virus has been shown to survive for a long time in such material away from the body. Scott and Simon (1923), using a scarified rabbit cornea, reported isolation of variola virus from nasopharyngeal secretions collected on the 23rd and 31st day of disease in two patients, when the skin lesions had already disappeared in each case. Similar results were reported by Friedemann and Gins (1917). We have not found any further satisfactory reports confirming their results, and did not examine material after the skin lesions had cleared. These findings are not supported by epidemiological observations and have been disregarded in quarantine regulations.

Arising out of these investigations is the question when and why patients are infectious in the early stages of smallpox. Although in a few countries patients are considered to be infectious in the incubation period,

almost all workers consider that infectivity is greatest in the pre-eruption period and during the first appearance of the rash. Cases are on record of infection contracted from patients who died before they developed a focal eruption, but one wonders whether oral lesions were looked for in these cases. With this in mind, we thought it would be relatively easy to recover virus from nose and throat swabs or garglings. To our surprise we obtained the results seen in table I. Positive results were obtained only in two patients: one on the 2nd day of the rash, and one on the 3rd day, when ulcerating lesions were probably present in the mouth. Garglings and nose and throat swabs collected from two patients 4 and 3 days before the appearance of rash, from one patient 1 day before, two on the same day as the first rash, two on the 2nd day, and one on the 3rd day of rash, were all negative. All negative membranes received another passage and were negative. A very small amount of virus was recovered from a swab inserted through a cannula into the lung of Mrs. A after death, this might have been due to contamination from blood or skin during manipulation. (These results are in marked contrast to the 50% recovery rate of poliomyelitis virus from the pharynx of patients in the early stages of that disease, the comparatively insensitive monkey being used for test culture.) The egg culture was capable of detecting 2-3 living virus particles, hence these patients with negative cultures were either not excreting virus at all or were doing so only intermittently. Possibly some inactivator may be present in some salivary secretions. None of these patients gave rise to known secondary cases except Mrs. B who infected her husband and their daughter, both of whom were unvaccinated at the time of exposure.

DISCUSSION

How can we interpret these results in relation to infectivity of the patient in the early stage of smallpox? When variola was inoculated intradermally for vaccination in the pre-Jenner vaccination period, the incubation

could be interpreted in a similar manner. The particular disposition of connective tissue at any one time might be regarded as the resultant of an equilibrium state between the deposition and the removal of connective tissue. In progressing fibrosis this equilibrium is presumably disturbed, so that connective tissue is not being removed as rapidly as it is being formed. When this excess is removed—for instance under the influence of cortisone—the original state of equilibrium can be resumed only if, during the time of treatment, the excess connective tissue is removed at a greater rate than normal, while new connective tissue is being formed at the normal rate. This raises the question of the mechanism which stops resorption proceeding beyond a certain point. One could speculate that the normal equilibrium is regained when the excess tissue has been removed, or that all connective tissue is removed or remodelled while new connective tissue is being formed. The first possibility would require that the excess connective tissue should be somehow different from the normal—for instance in its state of polymerisation. An alternative explanation of the effect of cortisone would require that it acts by inhibiting cellular activity to the extent of interfering with deposition of formed elements. Neither interpretation would of course exclude a direct effect of cortisone on the hepatic parenchyma, as shown, for instance, by the increased amount of glycogen present even after twenty four hours' starvation in cortisone treated rats.

SUMMARY

Carbon tetrachloride causes hepatic fibrosis in rats. This change is inhibited if cortisone is given at the same time.

I wish to acknowledge the assistance of Dr Isidore Gersh, and the support of the Commonwealth Fund, the American Cancer Society, and the Wallace C and Clara A Abbott Memorial Fund of the University of Chicago.

A WALKING-PLASTER APPLIANCE

D G WRIGHT

M.B. Glasg., F.R.C.S.E

ASSISTANT SURGEON,

ROYAL HOSPITAL FOR SICK CHILDREN, GLASGOW

The appliance shown in figs 1-3 has been used with unvarying success in the past four months. It is composed of hard rubber with a core of asbestos. The front, sides, and back are vertical and continuous, apart from four slits which pass downwards from the upper edge to terminate an inch from the sole (fig 1). Two of these slits, one on either side of the front, enable the front to be hinged down as a tongue, and the same two slits, in addition to a further slit in each side-wall, allow the sides to be drawn together over the tongue with a leather lace. A leather lace is recommended as encountering least frictional resistance from the rubber lace holes which are placed at regular intervals beneath and parallel to the upper edge. The sole is rigid and has a flat superior aspect. The inferior aspect presents an uneven curve from heel to toe, the apex of the curve lying at the junction of the posterior third and anterior two thirds of the length. The sole is provided with a non skid tread. A range of sizes has been devised to apply to patients of all ages.

ORTHOPÆDIC ADVANTAGES

Radiography—There is minimal interference with radiography through the plaster, because there are no side irons or extra plaster for attachment of the appliance and the appliance can be removed with ease.

Gait—There is a smooth heel-and toe gait without lurching, bobbing, or rotation of the plastered limb, and there is a reasonable length of pace with either leg (fig 2).

Adaptability—Variation in position of ankle or knee of the plastered limb is readily compensated by placing pads of orthopaedic felt inside the footpiece under the forefoot or heel of the plaster. A fit has not been effected until the patient can balance with ease on the plastered limb alone (fig 3).

Balance—The appliance allows the patient to walk upstairs or downstairs, and to board or descend from buses with minimal difficulty, and enables a patient with both limbs in plaster to walk with ease.

UTILITARIAN ADVANTAGES

Easy Production and Moderate Cost—The shape of the appliance is aimed at allowing easy production by moulding. The cost is naturally influenced by the ease of production and by the fact that no additional plaster bandages are required for its application.

Light Weight—The 8 in. size, for example, weighs 10 oz.

Durability—The composition used is particularly resistant to wear and tear and gives promise of longevity.

Protection—The appliance is as watertight as an outdoor shoe and allows the patient to wear a sock or a stocking over the plaster.

Fit—The yielding nature of the rubber "upper" allows of reasonably accurate fitting of all plastered limbs. The sizes vary from 6 in. to 12 in. long with a difference of 1 in. between each size, and no variation in width is required for any one length.

Safety—The non skid tread protects the patient from any tendency to slip.

Bed Linen—The appliance is removed with the other outdoor garments when the patient goes to bed, and the bed linen is neither soiled nor damaged.

MECHANISM OF THE APPLIANCE

Balance on an immobilised limb alone is most easily achieved when the hip, ankle, and area of contact with

TABLE I—DETAILS OF EXPERIMENTS WITH CARBON TETRACHLORIDE (0.1 ML., SUBCUTANEOUS, TWICE WEEKLY) AND CORTISONE (SUBCUTANEOUS) RATS TREATED WITH CORTISONE WERE KILLED TWO DAYS AFTER THE LAST INJECTION

Group	No of rats	No of CCl ₄ injections	Days killed after last CCl ₄ injection	Cortisone
1	4	23	2, 5, 9, 13	Nil (control)
2	5	26	3-4	Nil (control)
3	4	33	3-4	Nil (control)
4	4	26	3-4	15 mg/day-4 days 10 mg/day-8 days 15 mg/day-4 days
5	3	33	3-4	3 weeks later 7 mg/day-9 days

the number of rats and their treatment are given in table I. Injections with carbon tetrachloride were continued throughout the period of administration of cortisone to avoid complication of the experiment by spontaneous reversion to the normal. The dose of cortisone was undoubtedly excessive.

All rats were starved for one day before killing, in the hope of freeing the liver of glycogen. The rats were killed by bleeding, and small pieces of the liver were fixed by freezing and drying for fine detail, and by immersion into neutral formalin Zenker for general morphology and fibre structure. The frozen dried material was embedded in paraffin; sections were cut at 20 μ , and stained by the Hotchkiss method to demonstrate the basement membrane and related substances. Material fixed in the customary way was embedded in paraffin and stained with hematoxylin and eosin for general survey, and with Mallory azan, and Bielschowsky silver stain, for fibres. In contrast with the controls, the liver of cortisone treated rats was found to be rich in glycogen. As this is also stained by the Hotchkiss method, it obscures the glycogen of the basement membrane. To avoid this difficulty it was necessary to treat another series of frozen-dried sections with 95% alcohol overnight, and incubate with saliva for 80 minutes and then stain in the usual manner by the Hotchkiss method.

RESULTS

Changes induced in the liver of rats by carbon tetrachloride agree with Cameron and Karunaratne's general findings and in respect of collagen to some extent with Fiessinger's (1945) description. They consist of vacuolation (with occasional "ballooning") of the hepatic cells, the presence of mitotic figures, increased cellularity of the stroma ("round" cells, fibroblasts, and pigment laden macrophages), the appearance of coarse collagenous bundles and reticular fibres, and in some cases marked structural alterations of the lobules. These effects of carbon tetrachloride varied from rat to rat, as is shown in table II.

Of particular interest are the changes which become apparent in livers fixed by the freezing drying method and stained for glycoproteins. This method makes it possible to see clearly the basement membrane of the sinusoids, which in the normal fasted animal appears as a delicate, pink staining, finely fibrillar membrane, in places hardly visible, more conspicuous in others. The cytoplasm of the hepatic cells contains numerous fine pink granules, arranged presum-

TABLE II—THE EXTENT OF THE CHANGE IN COLLAGEN AND RETICULAR FIBRES (FROM "NORMAL" (+) TO "MARKED" (+++)) IN RATS INJECTED WITH CARBON TETRACHLORIDE (CONTROL) AND AFTER TREATMENT WITH CORTISONE

Change in fibres	Collagen		Reticular fibres	
	Number of rats		Number of rats	
	Control	Cortisone	Control	Cortisone
+	2	5	2	4
++	5	0	4	1
+++	5	1	5	1
++++	1	1	2	1

ably in the vicinity of the bile canaliculi. Finally this method brings out quite clearly changes in the number, size, and stainability of cytoplasmic granules of sinusoidal cells. This brief description is based on the study of the frozen-dried liver of many normal, though younger, animals than the ones used in the present series.

In the majority of the animals treated with carbon tetrachloride the basement membrane seems to be thickened, so that it can now be seen with great ease. The number of sinusoidal cells containing granules, and the number of granules in each cell, are both increased. In the vicinity of the larger vessels there are many similar, though larger, cells which in addition contain clumps of coarse brown granules. A second group of connective tissue cells can be made out, these are long and spindle shaped, with an oval nucleus and granules which appear to be identical with those described in fibroblasts by Gersh and Catchpole (1949). It is of great interest that identical granules were seen in some cells in the sinusoids.

The general effects of administration of cortisone confirm those reported in the literature, rapid and progressive loss of weight, marked decrease in the size of the spleen, and a noticeable decrease in that of the adrenal. The livers of rats injected with carbon tetrachloride had a slightly irregular margin and their consistency was rubbery. The liver margin was smooth and rounded and the parenchyme was soft and readily cut in two of the seven rats given cortisone in addition. A third cortisone treated animal had a granulomatous liver resembling that described by Antopol (1950). Microscopically, the most prominent feature of the livers of five of the seven rats given cortisone was that they contained considerably less collagen and reticulum than in the animals given carbon tetrachloride alone. In fact, these components were within the normal range (table II). There was also a considerable reduction in the degree of round cell infiltration, and a notable lack of eosinophils. Less constant were the number of mitotic figures and the degree of vacuolation of hepatic cells.

Unfortunately, the large amounts of glycogen in the livers of the cortisone treated, fasted animals did not allow a direct comparison of the basement membranes with those of the carbon tetrachloride controls, except in one animal where small groups of glycogen free cells were present. The basement membrane in relation to these cells was very thin. Removal of the interfering glycogen with saliva leads to swelling and reddening of the basement membrane of the hepatic sinusoids of rats injected with carbon tetrachloride alone. Of the seven cortisone treated animals, five showed thinning of the basement membrane, including the one animal which by means of the other stains had shown fibrosis and granulomatous nodules to be present in the liver. In a sixth there was a doubtful thickening and the seventh was indistinguishable from the controls. Thus we see again the same trend towards the thinning and decrease of the connective tissue elements after cortisone which was brought out by means of the other stains.

DISCUSSION

The inhibition by cortisone of the formation of fibrous tissue would be a desirable effect in those diseases where fibrosis plays a prominent part in the causation of the symptoms. The experiments just described, although not conclusive, seem to show that such an inhibition and reduction of connective tissue is feasible. This applies not only to the reticulum of the liver and the collagen of the portal spaces but also to the basement membranes of the sinusoids. Gersh and Catchpole have emphasised in their recent paper the plasticity of connective tissues and described changes which take place in various physiological and pathological conditions. These changes were interpreted as an expression of the varying degree of polymerisation of the ground substance which in some cases can be influenced directly by hormonal factors. The experiments described here

Duration of Test

The presence and degree of agglutination of sensitised sheep cells by a human serum, absorbed on normal sheep cells, depends to some extent on the time interval between setting up the test and reading the result. Table II shows the variations observed in the activity of four absorbed sera when the test was read after an hour at 37°C and again after eighteen hours at 4°C.

Although the titre of an absorbed serum is occasionally not affected, there is usually a twofold or fourfold increase in the titre when the test is read after eighteen hours as compared with one hour (serum A). Sera that do not agglutinate sensitised cells after an hour often do not do so after eighteen hours (serum B), but they may cause agglutination in low titre (serum C) or exceptionally in high titre (serum D). In tests of apparently healthy laboratory workers agglutination of sensitised cells was never seen after an hour, whereas agglutination in low titre was sometimes present after eighteen hours. Hence reading the test after eighteen hours necessitates the acceptance of an arbitrary titre above which a serum is considered abnormal or "positive". If, however, the test were read after an hour, agglutination of sensitised cells of any degree could be

TABLE I—AGGLUTINATION OF NORMAL AND SENSITISED SHEEP CELLS BEFORE AND AFTER ABSORPTION OF HETEROPHIL ANTIBODY

Serum	Absorption	Sheep cells	Serum dilutions						
			1/4	1/8	1/16	1/32	1/64	1/128	1/256
A	Before	Normal	+	+	+	0	0	0	0
	After	Sensitised	+	+	+	+	0	0	0
		Normal	0	0	0	0	0	0	0
B	Before	Normal	+	+	+	0	0	0	0
	After	Sensitised	+	+	+	+	+	+	+
		Normal	0	0	0	0	0	0	0
C	Before	Normal	+	+	0	0	0	0	0
	After	Sensitised	+	+	+	+	+	+	+
		Normal	0	0	0	0	0	0	0

Serum dilutions were carried to a titre of 1/8192 but no agglutination occurred beyond 1/256

considered abnormal. Moreover this method of estimating positivity would greatly facilitate the reading of the test.

To obtain further data on the influence of time on the result of the test it was decided to take readings after an hour at 37°C and again after eighteen hours at 4°C.

Effects of Variations in Haemolysin

Haemolysin will agglutinate as well as sensitise sheep cells, but the highest dilution at which agglutination takes place is lower than that at which complete haemolysis will take place in the presence of excess of complement.

In the technique of Rose et al (1948) and Heller et al (1949) twice the minimum haemolytic dose of haemolysin was used. But it may rarely happen that the agglutinin titre of haemolysin is as high as the dilution containing two minimum haemolytic doses, in which case the sensitised cells will be spontaneously agglutinated and the test vitiated. Moreover, since the haemolysin titre was estimated after an hour and the test read after eighteen hours, this rare danger of spontaneous agglutination was increased because during the longer interval the agglutinin titre of haemolysin was increasing.

Different batches of haemolysin may also affect the sensitivity of the test (table III).

TABLE II—EFFECTS OF TIME ON AGGLUTINATION OF SENSITISED SHEEP CELLS BY ABSORBED HUMAN SERA

Serum	Reading	Serum dilutions					
		1/4	1/8	1/16	1/32	1/64	1/128
A	1 hour	+	+	+	+	0	0
	18 hours	+	+	+	+	+	+
B	1 hour	0	0	0	0	0	0
	18 hours	0	0	0	0	0	0
C	1 hour	0	0	0	0	0	0
	18 hours	+	+	+	+	+	+
D	1 hour	0	0	0	0	0	0
	18 hours	+	+	+	+	+	+

Serum dilutions were carried to 1/8192 but no agglutination occurred beyond 1/128.

Similar serum dilutions did not agglutinate normal sheep cells in each of the eight tests.

To demonstrate this, a single batch of sheep cells was divided into six lots, each of which was sensitised by a different batch of haemolysin at a dilution containing one minimum haemolytic dose. Each lot of sensitised cells was then set up against the same absorbed human serum, and the resulting titre read after incubation for an hour at 37°C. In haemolysins A and B the ratio of agglutinin to haemolysin titre is relatively high, and in both cases the sensitivity of the test, as estimated by the titre of the serum, was slightly increased. Haemolysins C, D, E, and F produced the same degree of sensitivity even though their haemolysin titres varied from 1/800 to 1/4000, but the ratio of agglutinin to haemolysin titre was relatively low. The difference is slight but indicates nevertheless that the sensitivity of the test cannot be accurately controlled merely by using a constant dose of haemolysin to sensitise the sheep cells. In practice a haemolysin is chosen with the above facts in mind and then checked for its effect on the sensitivity of the test by using it with a human serum whose agglutinin titre for sensitised cells is known. The sensitivity of the test is thus controlled by reference to an arbitrary standard human serum.

With a sufficiently wide margin between agglutinin and haemolysin titres, the sensitivity of the test is not appreciably altered whether one or two haemolytic doses are used to sensitise the sheep cells. With further increases in haemolytic dose the test becomes gradually more sensitive.

TECHNIQUE ADOPTED

From a consideration of these findings the following technique was evolved for demonstrating the activity of human sera towards sensitised cells.

Preparation of Reagents

Commercial defibrinated sheep blood, four days old, is washed three times in physiological saline solution. The

TABLE III—EFFECTS OF DIFFERENT HAEMOLYSINS ON SENSITIVITY OF TEST

Haemolysin	Haemolysin titre (HT)	Agglutinin titre (AT)	AT/HT	Titre of test serum for sensitised cells
A	1/2000	1/800	0.30	128
B	1/200	1/50	0.25	128
C	1/4000	1/400	0.10	64
D	1/1800	1/100	0.05	64
E	1/800	1/50	0.06	64
F	1/1400	1/200	0.14	64

packed-cell volume is determined and a 2% suspension prepared. 0.85% saline solution is used as the diluent for all reagents.

Rabbit anti sheep erythrocyte serum (haemolysin) is prepared by any of the standard techniques (Medical Research Council 1918). It is stable for months if stored frozen.

Preserved haemolysin has not been satisfactory. The titre of the haemolysin is determined as follows: 0.25 ml of

the ground are in the same vertical line. The area of contact when the appliance is fitted is the apex of the sole curve, slightly compressed by the patient's weight. The site of this apex on the sole ensures that, when the upper surface of the sole is horizontal, a part at least of the small weight bearing area lies vertically under the ankle joint in the great majority of cases, and to effect the necessary balance requires only minor adjustment, if any, to bring the hip into the same vertical line. This is achieved automatically in a below-knee plaster in which the ankle joint is approximately at 90°, or in an above knee plaster in which the surgeon has produced a degree of dorsiflexion at the ankle to counteract the degree of flexion at the knee. In these cases the appliance is fitted and the patient can immediately balance on the plastered limb alone. If a "hard soled" plaster is desired the patient is instructed to refrain for twenty four hours from weight bearing.

If, either by accident or design, the angle of the ankle (short plaster with considerably plantar-flexed ankle) or of the ankle and knee combined (long plaster) causes the hip to be behind the vertical line passing through the apex, the patient, when standing on the plastered limb alone, will tend to roll backward. Adhesive orthopaedic felt is then placed inside the heel of the appliance until the heel of the plaster is raised sufficiently to rotate the hip forward into the desired plane. Conversely, if the hip lies anterior to the desired line (short or long plaster with considerably dorsiflexed ankle), adhesive felt is placed in the forefoot of the appliance until the plastered forefoot has been elevated sufficiently to rotate the hip back into line. Easy balance has thus been achieved in either case without any alteration of the plaster.

The thickness of the sole at the apex is such as to ensure reasonable equality in length of the plastered limb with that of the sound limb if normal footwear is worn. But adjustment for a high heeled shoe on the sound limb or for relative shortening of the plastered limb requires only the insertion of pads of felt inside the entire length of the sole to raise the plastered foot to the requisite distance from the ground.

The balance, equality in length of limbs, and the fact that the apex of the curve is only from $\frac{1}{4}$ in (in the 6 in size) to $\frac{1}{2}$ in (in the 12 in size) produce an even heel and toe gait without lurching, "corkscrewing," or bobbing up and down, while at the same time the patient has a reasonable length of pace with either limb.

I wish to thank my chief, Mr Matthew White, on whose patients the appliance was elaborated, the makers, Messrs George McLellan & Co., Glasgow Rubber & Asbestos Works, Maryhill, Glasgow, and particularly Mr Dee and Mr Armour of that firm, and Mr Evatt and Mrs Stewart of the Royal Hospital for Sick Children photographic department. Photographs were taken with a 200 joule electronic flash lamp producing a flash of $\frac{1}{1000}$ second duration. The method of taking was to walk the child up and down a predetermined line on the studio floor on which the camera had previously been focused, and to trip the flash (and expose the plate) when he arrived at a point opposite the lens axis. Owing to the great intensity of light and extreme short duration of exposure it was thus possible to obtain a perfectly natural unposed walking photograph indoors.

SERUM FACTOR IN RHEUMATOID ARTHRITIS AGGLUTINATING SENSITISED SHEEP RED CELLS

J BALL

M.B., B.Sc. Manc

RESEARCH ASSISTANT IN THE DEPARTMENT OF RHEUMATISM RESEARCH, UNIVERSITY OF MANCHESTER

Rose et al (1948) accidentally found in a case of rheumatoid arthritis that the patient's serum agglutinated sensitised sheep erythrocytes in high dilution, whereas normal sheep cells were agglutinated only in low dilution. They subsequently devised a technique for determining the agglutinin titre of human serum for normal and sensitised sheep cells. Their method was essentially as follows.

A 1% suspension of sensitised sheep cells was prepared by adding to a volume of a 2% suspension of washed normal (non sensitised) sheep cells an equal volume of a rabbit anti sheep erythrocyte serum (haemolysin) containing two minimum haemolytic doses. The serum under test was inactivated at 56°C, and two series of doubling dilutions in 0.5 ml volumes were made. An equal volume of a 1% suspension of sensitised sheep cells was added to one series, and an equal volume of a 1% suspension of normal sheep cells to the other. The results were read after incubation at 37°C for an hour and refrigeration at 4°C overnight. When the agglutinin titre for sensitised cells was sixteen times or more the agglutinin titre for normal cells the test was considered positive.

After examining sera from 110 patients, including 51 cases of rheumatoid arthritis, Rose et al suggested that the test might be a useful diagnostic aid in this condition. This opinion was generally confirmed by Sulkin et al (1949) and Jawetz and Hook (1949), both using the above technique in 148 and 160 cases respectively.

FACTORS AFFECTING AGGLUTINATION

A critical examination of this technique shows that three important points had not been considered in devising the test: (1) the rôle of heterophil antibody, (2) the duration of the test, and (3) the effects of variations in haemolysin.

Rôle of Heterophil Antibody

The agglutination of sensitised cells may be due to two distinct factors, one of which, heterophil antibody, can be absorbed on normal sheep or ox erythrocytes, whereas the other cannot. Table 1 shows the results obtained in testing different human sera on normal and sensitised sheep erythrocytes before and after absorption on normal sheep cells.

Absorption of serum A leads to complete loss of agglutinating activity for both normal and sensitised sheep erythrocytes. Serum B similarly treated shows complete loss of agglutinating activity for normal sheep cells, but its activity for sensitised sheep cells is unaffected. Serum C behaves like serum B, though its titre for sensitised cells is lower. In the case of serum B and C, absorption on normal ox cells or repeated absorption on normal sheep cells does not affect the agglutinin titre of the serum for sensitised sheep cells. Since heterophil antibody is not increased in rheumatoid arthritis, these results indicate that the high agglutinin titre for sensitised cells observed by Rose et al (1948) in some of these cases was due essentially to this new serum factor. Moreover it seemed likely that if rheumatoid arthritis had any specific activity for sensitised sheep cells it would be concerned with this serum factor, and therefore the presence of heterophil antibody in the serum under test would be both unnecessary and

“ the hospital allowed Oliver to come home. When he turned to Julia he said ‘I was afraid all the time of what they would do to me next, but I got out before they could do the worst thing of all. I kept hearing them say I would have to have my bowels opened.’—‘Oh, the terrors children suffer needlessly,’ Julia cried. ‘It only means Syrup of Figs or something of that kind.’ I wish I had

rheumatism Some of the cases were repeatedly tested at intervals, but a positive result was never obtained

Group 7 consisted of 134 cases of non arthritic disease (table vi) All gave a negative reaction

Group 8 consisted of 87 miscellaneous medical and surgical patients, all but 1 of whom gave a negative reaction.
